SIR: An editorial in your issue of the 18th inst., based on an address recently delivered before the American Dermatological Association, by Dr. Prince A. Morrow, does this college, and, I believe, many other medical colleges injustice. The author states that "there is no medical school in this country in which the study of diseases of the skin is obligatory; in none is a knowledge of this important branch of medicine required as a condition of graduation; the professor in this department is not allowed to interrogate students, and has no voice in deciding upon their qualifications for a degree."

Will he allow me to state that in the Albany Medical College the study of diseases of the skin has been obligatory for the past ten years, during which time a professorship of dermatology has existed in this college, and that a "knowledge of this important branch" *is* "required as a condition of graduation." The professor in this department holds regular examinations during and at the close of the term, and has a voice in deciding upon the qualifications of students for the degree of Doctor of Medicine.

Yours respectfully,

WILLIS G. TUCKER, M.D.,
Registrar Albany Medical College.

October 27, 1890.

FOOT-AND-MOUTH DISEASE.

A REPLY TO DR. STICKLER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I am obliged to Dr. Stickler for calling my attention to the MEDICAL RECORD for December 10, 1887, containing the report of the Meeting of the Academy of Medicine, which I now read for the first time. I can now see how Dr. Stickler has been misled, but it is not

so easy to see why he refuses to accept my unqualified denial that I ever said that foot-and-mouth disease "had at different times attacked nearly all the people of Europe." As the case now stands, it is not a question of veracity affecting Dr. Stickler or myself; it is simply a question of whether a reporter has made a mistake in condensing the remarks made at a public meeting on a subject with which he was unfamiliar. Dr. Stickler is entirely mistaken in supposing that the MEDICAL RECORD furnished a *verbatim* report of my remarks at the meeting; the reporter will not claim this. Dr. Stickler should therefore consider that it is not an uncommon experience that a reporter who undertakes to condense his notes on an unfamiliar topic runs some risk of misrepresenting the speaker. It does not by any means follow, however, that he will therefore misrepresent all speakers at the same meeting, as Dr. Stickler asserts.

To clear up the matter, however, I beg to submit the subjoined letter from Dr. L. McLean, of Brooklyn, who spoke to the point in question at the meeting of the Academy, and who would therefore recall, even better than others, whether the position he took was contested by me. He says:

"DEAR SIR: Yours of October 18th duly received, wherein you state that Dr. Stickler charges you with having said, at a meeting of the Academy of Medicine (where he read a paper on foot-and-mouth disease), that said disease had at times attacked nearly all the people of Europe. Dr. Stickler, in his paper, referred to this disease as being epidemic in Europe. I at once took exception to the term epidemic, and denied that it had ever so appeared, or in any other form but as an epizootic, and that one attack in the bovine tribe did not confer immunity from a second attack, but did, in reality, predispose it to a second attack, and that I had frequently known one animal to have three attacks within twelve months. With this opinion you perfectly agreed, and I do not believe that you, from your knowledge of this disease, could express the opinion above referred to. Yours truly,

"L. MCLEAN."

I quote Dr. McLean because, like myself, he has had an extensive experience with this disease in Europe, and because, as the result of such intimate acquaintance with the malady, he felt called upon to promptly contradict the allegation of its epidemic prevalence. Had I afterward at that meeting claimed such epidemic prevalence, his protest would have been made even more promptly and earnestly.

I can easily pardon Dr. Stickler for his blunder, but it is hard to understand why he should persist in that blunder in the face of my pointed denial that I ever expressed myself in terms that would have shown the grossest ignorance of a subject which it has been the work of my life to teach.

Respectfully,

JAMES LAW.

New Instruments.

A CURETTE FOR THE REMOVAL OF ADENOID VEGETATIONS.

BY EDGAR HOLDEN, M.D.,

NEWARK, N. J.

THE very satisfactory results of treatment of adenoid vegetations in the vault of the pharynx, variously styled "hypertrophic posterior nasal pharyngitis;" "hypertrophy of the pharyngeal tonsil," etc., have naturally led to the invention of a great variety of instruments; and the very multitude of these suggests the probability that the one adapted to the majority of cases has not yet been found. The admirable chapter on this subject in Bosworth's recent work "Diseases of the Nose and Throat," describes perhaps all the instruments thus far presented; yet reflecting that after all the general tendency is to give preference to the rather crude method of removing the vegetations with the finger nail, or the finger curette of Capart of Brussels, it may be of interest to state that a very simple and efficient instrument, designed as a substitute for these, has been made for me by Reynders & Co., a drawing of which is herewith submitted. It is a flexible curette, shaped at the tip like the finger-nail, which by its elasticity adapts itself to the pharyngeal vault and can be rapidly used even on a rebellious child, without the aid of an anæsthetic. That this has been in my experience

applicable to the majority of cases, especially of the fimbriated and cushion-like varieties, is my excuse for calling attention to it. It may be superfluous to say that there are exceptional instances where Major's adenotome as modified by Delavan, the cautery loop, or the forceps of Lowenberg or Hooper, may be necessary, but for office use, this simple device has saved much time and annoyance.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 26 to November 1, 1890.

CONWAY, STEVENS G., Surgeon. Granted leave of absence for one month, with permission to apply for an extension of fifteen days, to take effect upon the arrival of Acting Assistant Surgeon A. P. Frick, at Fort Marcy. S. O. 112, par. 2, Department of Arizona, Los Angeles, Cal., October 24, 1890.

EWING, CHARLES B., Captain and Assistant Surgeon. By direction of the Secretary of War, the leave of absence granted in S. O. 131, September 22, 1890, Department of the Missouri, is extended fourteen days. S. O. 250, A. G. O., October 25, 1890.

EDIE, GUY L., Captain and Assistant Surgeon, Fort Douglas, Utah. Granted leave of absence for one month, on surgeon's certificate of disability. S. O. 80, Headquarters Department of the Platte, Omaha, Neb., October 27, 1890.

WOODRUFF, CHARLES E., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, relieved from duty at Fort Gibson, Cal., and will report in person to the commanding officer at Fort Missoula, Mont., for duty at that post, relieving Major Calvin De Witt, Surgeon. S. O. 249, par. 6, A. G. O., Washington, D. C., October 24, 1890.

DE WITT, CALVIN, Major and Surgeon. By direction of the Secretary of War, on being relieved by First Lieutenant Woodruff, will report in person to the commanding officer at Fort Hancock, Tex., for duty at that post. S. O. 249, par. 6, A. G. O., Washington, D. C., October 24, 1890.

WALES, PHILIP G., First Lieutenant and Assistant Surgeon. Relieved from station and further duty at Fort Huachuca, Ariz. Ter., and assigned to duty at San Carlos, Ariz. Ter., where he is now temporarily serving. S. O. 254, par. 13, A. G. O., Washington, D. C., October 30, 1890.

JARVIS, NATHAN S., First Lieutenant and Assistant Surgeon. So much of par. 2, S. O. 208, A. G. O., September 5, 1890, as directs him to report for duty at San Carlos, Arizona Ter., is revoked. On the expiration of his present sick leave of absence Lieutenant Jarvis will

report in person to the commanding officer at Fort Bayard, N. M., for duty at that station. S. O. 254, Mar. 13, A. G. O., Washington, D. C., October 30, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 1, 1890.

STEPHENSON, F. B., Surgeon. Detached from Receiving-ship Wabash, and wait orders.

MARTIN, H. M., Surgeon. Ordered to the Receiving-ship Wabash.

STONE, LEWIS H., Assistant Surgeon. Ordered to the Pinta.

ARNOLD, WILLIAM F., Assistant Surgeon. Detached from the Pinta, and granted two months' leave.

OWENS, THOMAS, Surgeon. Detached from the Coast Survey steamer Blake, and wait orders.

BLACKWOOD, N. J., Assistant Surgeon. Ordered to the Receiving-ship Vermont.

BOGERT, E. S., Assistant Surgeon. Detached from the Receiving-ship Vermont, and ordered to the Coast Survey steamer Blake.

MOORE, A. M., Surgeon. Detached from the Kearsarge, and ordered to the Naval Hospital, Mare Island, Cal.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 1, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	36	11
Scarlet fever	53	3
Cerebro-spinal meningitis	2	1
Measles	108	7
Diphtheria	57	22
Small-pox	0	0
Varicella	5	0
Pertussis	1	0

The Establishment of State Insane Asylum Districts.—In accordance with the provisions of section 1 of chapter 126 of the Laws of 1890, the following division of the State into State Insane Asylum Districts was made and ordered to take effect October 1, 1890: Utica State Hospital District—Counties of Albany, Fulton, Hamilton, Herkimer, Madison, Montgomery, Oneida, Saratoga, Schenectady, containing 1,476 insane patients. Willard State Hospital District—Counties of Alleghany, Cayuga, Chemung, Livingston, Ontario, Schuyler, Seneca, Steuben, Tompkins, Wayne, Yates, containing 1,024 insane patients. Hudson River State Hospital District—Counties of Columbia, Dutchess, Putnam, Rensselaer, Washington, Westchester, containing 1,159 insane patients. Middletown State Hospital District—Counties of Orange, Queens, Richmond, Rockland, Suffolk, Sullivan, Ulster, containing 988 insane patients. Buffalo State Hospital District—Counties of Cattaraugus, Chautauqua, Erie, Genesee, Niagara, Orleans, Wyoming, containing 1,148 insane patients. Binghamton State Hospital District—Counties of Broome, Chenango, Cortland, Delaware, Greene, Otsego, Schoharie, Tioga, containing 548 insane patients. St. Lawrence State Hospital District—Counties of Clinton, Essex, Franklin, Jefferson, Lewis, Onondaga, Oswego, St. Lawrence, Warren, containing 964 insane patients. The number of public insane patients in each of the above-named districts is given as it exists at this date.

At a Special Session of the State Commission in Lunacy, held at the Capitol, in the City of Albany, on the second day of September, 1890: It appearing that large numbers of the insane poor are deprived of the benefits of the intended care and treatment which the State Hospitals were instituted to provide for them; that much space at these institutions, originally provided for the accommodation of that class, is now occupied by private patients; that the law known as the State Care act reaffirms the policy of the State and declares the insane poor to be the wards of the State, and provides for the removal as rapidly as possible of those now remaining in the county poor-houses to the State Hospitals; therefore, be it ordered: 1. That on and after October 1, 1890, no private patient at any State Hospital be permitted to occupy more than one room for his or her personal use or behoof, or to command the exclusive services of an attendant; and, thereafter, there shall be no distinction allowed between private and public patients in respect to the scale of care and accommodations furnished them. 2. That on and after October 1, 1890, no private patient be admitted to any State Hospital, except in strict accordance with the statutes, as follows: "Whenever there are vacancies in the asylum" (State Hospital), there may be received "such recent cases as may seek admission under peculiarly afflictive circumstances, or which in his (the Superintendent's) opinion promise speedy recovery," and upon an order granted by the State Commission in Lunacy upon an application in writing, addressed to the Commission, of a near relative, guardian, or committee of the patient. 3. That this order shall not be held, except in special cases, to require the removal of private patients in custody in said hospitals on October 1, 1890. Also, the Commission having before it estimates and special reports from the Superintendents of the several State Hospitals and other interested persons concerning the charge to be made to counties of the State for the care and maintenance of insane patients in the said hospitals, and said Commission being required by statute to establish a charge for maintenance, which shall be the same for all the counties of the State; it is ordered: 1. There shall be charged for each patient in continuous custody under the commitment, or order, by which he is held, as follows: (*a*) For the first three years or less, the sum of four dollars and twenty-five cents per week; (*b*) for any period of time exceeding three years, the sum of two dollars and fifty cents per week. 2. The charge hereby established shall include food, clothing, breakage, and all other charges of any name or nature, and no greater charge shall be made under any circumstances whatsoever. 3. This order shall be in full force and effect on and after October 1, 1890, and shall apply to all patients in custody on that date.

Ill-health, according to the always cheerful Sir John Lubbock, is no excuse for moroseness. If we have one disease, we may at least congratulate ourselves that we are escaping all the rest. Sydney Smith, ever ready to look on the bright side of things, once, when borne down by suffering, wrote to a friend that he had gout, asthma, and seven other maladies, but was "otherwise very well," and many of the greatest invalids have borne their sufferings with cheerfulness and good spirits.

A New Way of Abusing Medical Charity.—The celebrated surgeon, Professor Billroth, of Vienna, was asked to perform an operation upon a Russian Jew, and he agreed to do it for a fee of two hundred and fifty guineas. On making the journey to the small town in which his patient lived, he was informed that the Jew had suddenly died. However, in order that he should not suffer loss by the transaction, the professor was asked whether he would treat five hospital patients for a fee of fifty guineas each. He accepted the offer, and did the work; and just as he was starting homeward he ascertained that one of the five patients upon whom he had operated was the Jew who was reported to have died.

THE AMERICANS AND THE TENTH INTERNATIONAL CONGRESS.[1]

BY A. JACOBI, M.D.,

NEW YORK.

ON August 4, 1890, during the first, and largest, general meeting of the Tenth International Congress, there were three universal and spontaneous outbursts of applause. The first and most sympathetic greeted the name of James Paget, and never was there an ovation more deserved. The second rang through the immense building when it was announced that the government of the French Republic had sent thirty-four official delegates, and that nearly one hundred and fifty more Frenchmen had joined the Congress. They had overcome political enmity and jealousy, disregarded a rather slighting reference to their "national insanity" of twenty years ago, and came with open hearts and friendly feelings, a large number of them men of fame and high rank. The third greeted the announcement of the fact that on the first day of the gathering, more than six hundred Americans were inscribed on the rolls. This recognition afforded to our name must have flattered the national pride of everyone of us who was present.

This hearty welcome was more than I had mustered the courage to expect. For, indeed, Americans visiting Europe on such occasions as this labor under certain difficulties. Europeans do not quite understand our country, its political and social configuration or its scientific attainments. If that be so even in Great Britain, both race and language being identical and mutual intercourse more frequent, how much less can we expect it to be known on the Continent. Besides, it is not always the best political, social, and scientific class of our fellow-citizens who travel extensively, and though it be not the crowd of the "profanum vulgus" that ought to tell in the estimation of the best spirit of their country, it does so tell. Now, the majority of medical Americans they know in Europe, and particularly in Germany, belong to one of two classes: either they are *bona fide* students, whom, being mere foreigners, they consent to matriculate even without the preliminary education rigorously insisted upon in their own young countrymen, or they are our young doctors who pass a few months or a year in European laboratories and clinics for the sake of special studies. It is these latter that are also the occasional participants in their national associations, where, nobody else being present, they are naturally considered the representatives of American medicine. Our best men travel little and talk less. Indeed, some of those who were most fit to represent us in the Congress kept in the rear, modest and retiring. Besides, the great opportunity America might have had to present to the view of the world whatever there is great and progressive in American medicine appears lost. For in the very number of the *German Medical Weekly* which was published in the week of the Congress you could, in the history of previous congresses, read the statement that the Washington Congress was unfortunately a failure, for which all of us, being Americans, are held responsible. Moreover, though English is read by a great many of the best men in Europe, the knowledge of our language is not so general as to insure a wide acquaintance with our literature through anything but the uncertain channels of extracts or translations. Nor are even these well selected. We are all aware that our medical journals are of as unequal rank as our schools, and not infrequently will you find a journal which is deservedly unknown among us quoted in Europe under the impression that it is a fair representative of American medical literature. Nor is the treatment Europeans receive at our hands always very courteous or considerate. The editorial remarks of a great New York weekly were quoted as unkind, inasmuch as the efforts to make the Congress international and Berlin a neutral ground for the whole world, did not appear to be appreciated by us. It must be admitted, though, they did not deem that Western journal worthy of serious consideration which spoke of the Tenth International Congress as a congress of snobs, and advised everyone of the forty thousand practitioners of the Mississippi Valley, "everyone superior to the leaders of the Congress," to stay at home.

Public opinion is often made or unmade by trivialities; sometimes, indeed, by personalities of an inferior nature. It was a source of complaint in Berlin that an American who had been honored with the request to represent our country by delivering one of the great addresses had neglected to see to it that his refusal reached the Committee of Organization in anything like due time. The proverbial courtesy of Americans was found wanting, and that at a time of feverish excitement and overwork. Such occasions are the very opportunities for those formerly Europeans who manage to rise, in their own estimation, and that of their former countrymen, by detraction of us. For there are those who do not immediately succeed, when they, our guests and future fellow-citizens, arrive among us, in impressing us with their superiority, or in being appreciated by us as they are by themselves, or in obtaining at once a lucrative practice and professional positions and honors. It is they who pay for the hospitality proffered by our country, with shoulder-shrugging insinuations and pitying remarks upon our crudeness and inferiority, our "mob rule," our "civilized barbarism," instead of aiding in the realizations of the national and cosmopolitan aims of the medical profession and science.

Nothing is so small as not to have some effect. Unfortunately, there is still so much national jealousy everywhere that faults and shortcomings in your neighbor beyond the boundary line are easily believed in, and slanderers and libellers are always busy. When I arrived in Germany, a newspaper article was shown me which was concocted by a sectarian practitioner formerly in New York, who detailed the inferiority of American medicine, schools, and practice to the horrified sanctity of the German public; and in the very week preceding the Congress, hundreds, or perhaps thousands, of pamphlets were distributed in Berlin, for the avowed purpose of insulting us and making us uncomfortable. The pseudonymous author, who appears to have lived, or lives, in Chicago, says, among a great many other things, the following:

"In reference to the transatlantic gentlemen, nothing is more out of place than indulgence. American tolerance, so frequently extolled, exists for Americans only. When about to travel they leave it at home. It is almost always the result of ignorance, indifference, and bad conscience. As the average American never cares for the history of a science, the majority of the

[1] Being an introduction to special reports of Delegates to the Congress before the New York Academy of Medicine, November 6, 1890.

transatlantic members of the International Congress are totally unacquainted with European institutions, labors, and scientific methods and their aims. Nevertheless, everyone of these gentlemen carries a paper in his pocket, easily compiled, wherewith to resuscitate the obsolete science of Europe."

In the same sheet the man asserts that forty-two per cent. of all the doctors in Chicago are professed abortionists and a great many followers of "Christian Science."

Some of the great Germans, with whose names everyone of us is perfectly familiar, denied being in any way influenced by such rubbish; but then, again, it was through them that I was informed of a New York specialist, and a fellow of this Academy, who was reported to have availed himself of his personal intimacy with the officers of the Associated Press for the purpose of having his Congress paper served at the breakfast-tables of a million of American households on the day of its delivery. That was a week before the opening.

Thus, you see, Mr. President, American medical gentlemen may meet with difficulties in the face of such occurrences. Still, though they are as human on the other side of the Atlantic as we on this, the facilities of communication between the continents have become such as to enable those wishing to see and know the truth that the time when American medicine was merely receptive and imitative has long passed by, and that we have entered the arena as co-operating peers. They were, indeed, anxious to have us and secure a large American attendance. In order to accomplish that end the organizing committee appointed an American committee, which was to enlist universal sympathy in our country. No time was to be lost, and the first ten medical men who expressed their willingness to serve were appointed. The territorial jealousy, one of the most marked American littlenesses, which found its way into print several times, has obliged me to explain publicly, in the May meeting of the Association of American Physicians, why that committee consisted of Stewart, Fitz, Lusk, Draper, Hun, Pepper, Busey, Osler, and Peyre Porcher. Will the Western gentlemen who found fault with the committee, and heaped vituperation on the mode of its composition, tell us that the names selected did not deserve the honor conferred upon them, or that there are better ones among us? Does American medicine begin at the Alleghanies or the Sierra? Or will you gentlemen of Ohio, Mississippi, or Nevada, tell us which of the forty-four stars of the glorious flag is the one you claim as yours? Yours are the forty-four, so they are ours. Are your minds not big enough, your hearts not large enough to embrace the love of, and the pride in, the whole flag of America?

A further proof of the anxiety to secure the co operation and good-will of the Americans was given by the Berlin committee in this, that they insisted upon one of the public addresses in the general meetings being delivered by an American. Weir Mitchell having declined in time and courteously, and Osler not being within reach, I was telegraphically directed to select an orator. The choice of Horatio C. Wood was heartily approved of in Berlin and elsewhere. Again, a few have asked why a New Yorker could not have been honored with that commission? That question is answered by some other queries: Do you know of a better man? Is America bounded by the East and North Rivers? And lastly, has New York forgotten that she can afford to be courteous and generous?

More, a few weeks only before the meeting of the Congress the American orthopedists expressed the desire that there should be a separate section of orthopedics. When I, then already in Europe, was notified of that request by the Chairman of the Orthopedic Section of this Academy, and expressed my fear lest it might be too late to make arrangements for that change, I was by returning mail informed by the Secretary-General that the request was at once granted by the Committee of Organization, on the ground that my countrymen must know best what suited them and their scientific labors.

Again, the organization of the Congress was not completed without the election of an American vice-president, John S. Billings, and an American, M. Allen Starr, as one of the two English-speaking secretaries, and a large number of American vice-presidents of sections. And lastly, when, on the third day of Congress and in the second general meeting, the hour grew late and the audience melted under the hot sun, Dr. Wood's address was, out of consideration for the Americans, postponed to be the first topic of the third meeting, though the hour and arrangements and printed preparations had to be changed accordingly.

All this was meant, and was believed to suffice, to make every American feel at home. If it did not succeed, it ought to have accomplished that end. But I have been told that disappointments have been keenly felt and complaints been uttered.

When an English paper was read, many have been reported to have left the room. Many essays were not read at all, some were not allowed the time required by the authors, some men would read beyond the legal limits. Such comments are natural, but also their causes. The unprecedented number of papers offered at a late date, and too courteously accepted, and some acoustic disadvantages of many of the audience halls, are among the causes of disappointments, which are unavoidable in everything human. The experience of the past can furnish remedies in the future. However, when one man complains that he was not one among the five per cent. of members who could be admitted to the court reception in Potsdam; another, that he had to pay for his share of the section dinner on the evening of Wednesday, the 6th, proclaiming that matters were different in Washington, where no foreigner paid anything; it proves one of two things, either that there were those who went more for the incidental appurtenances of the Congress than the Congress, or that our national failing, which is a highly developed emotional hyperæsthesia, was rather demonstrative. I can assure those who are finding fault with the scantiness of their enjoyments that I know of one at least who neither shared in the entertainment in the City Hall, for which Berlin paid 80,000 marks, nor danced at any of the five balls, nor imbibed the music and songs in eleven languages, and as many beverages, at Kroll's, and—did not feel the worse for it the following mornings. If I have any fault to find, it is with the overflow of entertainments, the excess of generosity, the multiplicity of luncheons, dinners, and receptions, the waste of money in the vast number of public and private social gatherings.

If there ever were hosts spending unstintingly—aye, squandering—money in the service of unlimited hospitality they were the profession as a whole, and the single medical men of Berlin.

In connection with this fact let me make a remark, which is dictated by no cavilling spirit, that I have too many reasons to appreciate the universal kindness and untiring hospitality of the great and gentlemanly members of the Berlin profession, who were bent on nothing so much as rendering the sojourn of the foreign guests comfortable and pleasant. I must here mention the names of Virchow, Bergman, Waldeyer, Gerhardt, Henoch, Martin, and Leyden, and his accomplished wife, the Chairman of the Ladies' Committee, and could name a host of others. Many of us have found it impossible to respond at the same time to the requirements of actual congressional duties and the urgent demands of hospitable courtesy. In this, also, there is discomfort and loss for the individual member. But the matter has a very much more important aspect. An excess of social entertainments on one hand, and the accomplishment of the end for which the International Congress is convened on the other, are incompatible at a certain point. Too many feasts interfere with legitimate work. The expectation of a good

time may—if I must not say it does—invite the attendance of many, of hundreds, perhaps of thousands, who would not go for the sake of work. On the other hand, those who have gone for the latter are liable to feel sorely disconcerted. Thus it has happened—at least this disappointment can be held in part responsible—that the national associations have suffered from the persistent absence of those who do not wish to lose great opportunities; and that all over America, Great Britain, France, Germany, and other countries there have been formed by dissatisfied men, who place scientific work over any distractions, be they ever so pleasant, special societies, the objects of all of which ought to have been accomplished in the sections of the general bodies. It would be a sad development if the same tendency were to grow up in international congresses. This very moment, there are already in existence an international ophthalmological and an otological congress. It would be the fault of the management of international medical congresses, if other specialities, or doctrines, should follow the example, for no other reason than the predominance of the social over the scientific element. If the latter cease to rule the great men of science will stay away, and the holiday-seekers and a few ambitious office-holders will remain. *Experientia docet.*

It is only a wealthy city and rich professional men who can entertain as Berlin did. For such hospitality as was displayed there you require large and generous hearts, ample and well-filled purses. There are but few communities like her. If the habit of prodigality becomes persistent we shall be received in future with misgivings on the part of our hosts, who must fear lest their efforts fall short both of the results of predecessors and the expectations of the guests. Let these two calamities occur—viz., the absence of the best men of all nations, and on the part of cities and men hesitation to request our coming—what will become of the International Congresses?

And where is the prevention of the danger alluded to? Here: Let the social entertainments be reduced to a minimum. Then any city with ample hotel accommodations will be able to receive us, though we be thousands. Then those bent upon pleasure only will seek it elsewhere. Then the numbers will no longer be unwieldy and shapeless. Then the men looking for work, and for the men who work, will be eager to come and see and be seen, to teach and to be taught.

The unprecedented success of the American Congress of Physicians and Surgeons, the first meeting of which was held in Washington, in September, 1888, tells its own tale and exhibits the proof of what I say. In my mind there is no doubt that its second meeting, in September, 1891, will be equally successful; its three days will be dedicated to work, and the official social entertainment limited to a plain subscription banquet. In that way neither the lawful work of the Congress nor private intercourse and hospitality are interfered with.

It may appear invidious to mention the co-operative services rendered by the members of the different nations represented in the various sections of the Congress. Still as we generally have a good opinion of ourselves, we are not afraid of looking back at our own contributions to the scientific material that was furnished. When we do so we have to admit, however, that but a small percentage of our seven hundred participated in the general work. It is true there was one who got himself delivered of quintuplets; fortunately, he had no equals, and he was not, as a medical journal reported, "taken in earnest." Still, there were a number of papers, not compiled, but original. The Orthopedic Section was American to a great extent. The Neurological had a very fair representation from our country. The Gynecological and Pediatric Sections were not without American contributions. The Surgical was supplied with papers which were highly appreciated, mostly from the West. Indeed, there were but few sections in which no American took part, though there were some in which no active work at all was furnished by us. The most redeeming feature was the meeting of the combined Laryngological and Pediatric Sections, in which the ingenuous, painstaking, and successful efforts of O'Dwyer were heartily applauded.

After all, however, the labor performed in the general sessions may be the principal, but is certainly not the only, object in view. An English journal has said that "congresses are not instruments of research;" and still, the transactions of all are replete with it. It is true a congress is not so much meant for new discoveries as for the broad dissemination of facts, hints, and ideas. A man—not being ubiquitous—may not take away with him many things new, but what he carries home is a new stimulus and encouragement.

In the Congress you saw a great many men whom you thought you knew, but since you listened to them and watched them while you listened and took their measure, you know better now. You saw and heard the living objects of your admiration, the moulders of professional thought in all countries; discoverers, teachers, laboratory workers, practitioners; those who, after hard work, create books by spontaneous generation out of their brains, and those who compile them not of their pigeon-holes; the eagles, the bees, and the moles—also the parrots, and that class of envious cuckoos who transfer other birds' eggs into their own nests. You found there is room in our great army for many men and many classes of men. You gathered encouragement from learning that even truly great men are still men and human; and that some degree of greatness is within the grasp of any man, in town or village, who will work for it intelligently, bravely, and honorably. All this is what a congress will teach those who consent to learn.

There is another lesson that is taught by a congress: The separation into twenty sections proves the endless and diversified branching of the grand old tree of medical science. Their working under the same roof, however, and under the same administration; their occasional combination for a common purpose; their gathering in general meetings, and their listening to the same addresses, with the same interest and profit—all this, in spite of the fact that some of the twenty appear to be threatened with the danger of degenerating into mere handicraft, proclaim louder than steeple bells that medical science is "one and indivisible, now and forever."

The Congress has conveyed to me, like its predecessors in Copenhagen and London, a great lesson, and furnished an elevating spectacle. Imagine, those of you who have not been present, thousands of medical men from all parts of the world, and speaking a dozen different languages, not perhaps endowed with the same erudition or mental or moral power, but moved by the same instincts and interests, and assembling at the same call and for the same special purpose. The great and the lowly, the old and young meet as brethren on the same platform, if not of equality, still of fraternity and solidarity. National jealousy and prejudice are shelved for at least a week, and the lesson is taught that brethren may live together peacably under the same roof, an example to the nations both of the present and the future. The man and the man of science are appreciated and loved, though political adversaries. Applause takes the place of hisses. The contest is no longer against each other but with each other, side by side, arm in arm, with the same weapons of the brain and soul against the common enemy of science and mankind, viz., physical deterioration and social misery. Thus the cosmopolitan spirit of coming centuries is foreshadowed and initiated by the co-operation of the men arrayed in the army of the noblest of all sciences and professions. Therefore, may no man who can prove an example to his peers in this or any other country, no man who can teach, none who can learn, none who can worthily represent his country in any capacity and do honor to America among foreigners—may no man, except for valid reasons, ever shirk his duty to attend an International Medical Congress.

THE SURGICAL TREATMENT OF TUBERCULAR LARYNGITIS.

By D. BRYSON DELAVAN, M.D.,

PROFESSOR OF LARYNGOLOGY IN THE NEW YORK POLYCLINIC.

THE proposition that severe tubercular disease of the larynx be treated by surgical, rather than by therapeutical, measures, is so radical and so at variance with long-established usage with us, as hardly to pass unchallenged, if indeed it fail to meet with active opposition. Until recently we have been taught:

1. That in tubercular laryngitis none but the mildest and least irritating measures should be employed. 2. That in certain exceptional cases such treatment may result in cure of the laryngeal symptoms; or even that a cure may in some rare instances be spontaneous. 3. That after a certain stage in the progress of the disease the only possible means of controlling its painful symptoms is by the employment of anodynes and sedatives.

These principles, as a rule, have been accepted, and it has been conceded that genuine tubercular laryngitis, in its more severe manifestations, is a disease incurable itself, and certain, sooner or later, to be attended with great suffering to the patient.

In the light of recent investigations, however, it appears that our views, regarding several important details in the pathology and treatment of tubercular laryngitis, should be carefully revised, if not largely modified. For, be it remembered, that since the time when mild topical treatment, pencilling with nitrate of silver, and applications to the tuberculous ulcers of iodoform were first suggested, great advances have been made in our knowledge of the true character of tubercular disease in general, and in its successful management in other parts of the body. The presence of a specific germ has been demonstrated; the value of the surgical treatment of tuberculous joints and surfaces has been abundantly proved; and the successful results of these ideas have clearly suggested their adoption in the treatment of parts of the body to which they have not hitherto been applied. In short, the theory of the modern surgical treatment of tubercular laryngitis is based upon the broad general principles which govern us in the management of all tubercular disease.

This then, theoretically, is a distinct advance upon the methods in former use, under which, in genuine cases, the results as regards the larynx were almost invariably unfavorable.

It must be understood from the outset that we recognize two distinct forms of ulcer which may be associated with phthisis: 1. The catarrhal form, which under proper treatment may usually be healed; and 2. the true tubercular infiltration and ulceration, which, as a rule, runs a steadily unfavorable course, and which is not amenable to the ordinary means of cure.

Reference is not made in this paper to cases of the first class, *i.e.*, catarrhal ulceration of the larynx complicating phthisis, many of which have been known to recover, but to the typical tubercular disease, tending to severe œdema, quickly breaking down into ulceration and running through the various well-known stages of that most distressing affection, and which, by a general consensus of authority, is practically incurable. It is to the treatment of this latter form of disease that I would call attention, and beg consideration of the latest means suggested for its relief.

In this country the surgical treatment of tubercular laryngitis has seemed to meet with an indifferent reception, and to have made unsatisfactory progress. Heryng's method has been tried by several of our specialists, and not without success, as is proved by the admirable case presented by Professor Gleitsmann, of New York, at the Berlin Congress, the patient being a woman whose larynx has remained healthy for now two years after treatment. Little has been said here about the method, however, while Kranse's method, we believe, has been practically untried. It has seemed important, therefore, to present the subject prominently, and to urge that it be not allowed to pass unnoticed or to be dismissed upon theoretical objections, but that its principles be carefully studied, its application thoroughly tested, and its virtues, if virtues it be proved to have, verified and accepted. Thanks to the efforts and investigations of Professor Hermann Krause, of Berlin, and of Dr. Theodor Heryng, of Warsaw, we are now able to consider the question not as an untried theory, but in the light of improved methods, an ever-increasing mass of statistics, and the testimony of numerous unprejudiced witnesses.

The surgical treatment of tubercular laryngitis properly includes two varieties of operation: 1. The extrinsic, including tracheotomy, as suggested by Professor Beverley Robinson, of New York, and extirpation of the larynx; and 2, the intrinsic, or operations upon the soft parts of the interior of the larynx.

With the consideration of the first variety, this paper has nothing whatever to do. Tracheotomy can be nothing more than palliative, while laryngectomy is, with our present knowledge of the operation and its bad results, too radical to challenge serious attention.

It is with the second, then, that we have exclusively to deal, namely, with intralaryngeal operations upon the soft tissues of the larynx. Of these, again, there are four varieties: 1. Incision of the œdematous tissue, after the manner of Moritz Schmidt and others. 2. Heryng's method, by the subcutaneous injection of lactic acid into the soft tissues of the larynx when in a state of œdema. 3. Scraping of the laryngeal ulcer, as practised by Dr. Heryng. 4. Actual excision of the œdematous tissue, together with scraping of the ulcers, as recommended by Professor Krause.

The first method, incision of the œdematous tissue, has not met with general approval, both on theoretical and on practical grounds. The second is exceedingly painful, and, in the experience of the writer and others, has not yielded good results. We will confine ourselves therefore to the study of the third and fourth, premising that their employment is a secondary matter and adjuvant to a far more important element of treatment, namely, to the application of some agent which shall effectually destroy the last remnant of the tuberculous disease. Just as in other departments of surgery, both Professor Krause and Dr. Heryng work upon the theory that the diseased or infected tissue should first be as thoroughly as possible removed or scraped away, and the underlying parts then treated in such a manner that there can be no possibility of bacilli being left behind. For this purpose various agents have been used, such as menthol, iodoform, iodol, soziodol, pyoktanin, and others, with indifferent results. It is to Professor Krause, mainly, that we owe our knowledge of the value of lactic acid in these cases. He has found that this chemical, properly diluted and thoroughly applied to the diseased tissue, produces effects not to be attained by any other known agent, and that by its use brilliant results, considering the nature of the disease, may be gained. Dr. Heryng has also used the lactic acid treatment, applying it by first scraping a tuberculous ulcer with one of a series of small curettes which he has devised for the purpose, and then rubbing the acid well into the surface thus abraded.[1]

Professor Krause, on the other hand, uses one or more of a set of double sharp spoon instruments, which he has made for the especial object of cutting away any portions of diseased tissue which in his judgment may require removal, applying, after the operation, the lactic acid to the denuded part. Like Heryng, he is also in the habit of scraping tuberculous ulcers.

To explain these operations more in detail, the larynx

[1] Dr. Heryng exhibited at Berlin a case operated upon by his method in 1888 and cured. Excellent photographs of the larynx of his patient were taken by Dr. T. R. French, and exhibited with the reading of his paper.

is first anæsthetized by means of cocaine. In Dr. Heryng's operation the surface of one or more ulcers is then thoroughly scraped with the sharp curette, and, bleeding having ceased, the lactic acid is applied. In Professor Krause's operation one of his double instruments, with sharp spoon extremities, is introduced into the anæsthetized larynx, and the operation completed by the forcible closing of the blades of the instrument upon the selected tissue, and its subsequent removal. Professor Krause does not confine himself to the ulcers, but removes bodily the œdematous tissue as well, operating, if necessary, upon cases in which ulceration has not yet developed, and eradicating, as far as possible, all of the diseased tissue within reach. For the completion of the operation several sittings may be required.

The method of applying the lactic acid must be thoroughly understood. Indeed, the failure to obtain good results from it, sometimes complained of, is said to be due to lack of energy in its application. It is not enough that the surface of the ulcer or of the wound should be merely painted with the acid. Krause insists that it must be applied so intimately as actually to be incorporated with the parts under treatment, and directs that the application be made by saturating a pledget of cotton, wound upon a probe, with the acid, and then forcibly rubbing the diseased surface with this, in order that the destruction of the bacilli may be assured.

The strength of the lactic acid solution must be varied to suit the given case. From twenty per cent. to fifty per cent. is usually well tolerated and is sufficient for the purpose. Indeed, Krause believes that the effect of the solutions mentioned above is as energetic as that of the pure acid, while decidedly less irritating in sensitive cases. Some patients, however, seem to suffer much more than others under it, and it may be necessary, in exceptional cases, to reduce the strength of the solution as low as ten per cent. As a rule, the acid is not as well tolerated by the larynx as it is by the pharynx. Careful rubbing of the acid into the surface of a laryngeal ulcer, dispensing with the scraping process, will in many cases give excellent results.

The effect of the lactic acid treatment is very different from that of the treatment by other agents in common use; for while under some of the latter the surface of the ulcer will become tolerably well cleaned and apparently healthy, under lactic acid not only does this occur, but there is, as well, a marked tendency to cicatrization, which is distinctly not observed in the case of the first-mentioned drugs.

A case in which remarkably good effects were obtained from lactic acid was reported by the writer at a meeting of the American Laryngological Association, held in May, 1886. The indications for Krause's operation are, ulceration or œdema of the larynx sufficient to cause, *a*, laryngeal stenosis; *b*, pain and difficulty in deglutition; *c*, irritative cough.

It is absolutely necessary to the success of the operation that the disease be quiescent, *i.e.*, that there be no perichondritis and no active inflammation of the surface present. The latter should be of the characteristic gray color, devoid of the redness which denotes recent congestion. When these precautions are disregarded there is danger that an inflammation more or less serious and widespread may be established. Indeed, the only instances in which Professor Krause has reported unfavorable results have been in cases in which the presence of active inflammation was not recognized and respected, and in which the extension of the inflammation called for measures of relief.

Where the case is far advanced and the symptoms are very severe, the treatment described is contra-indicated, sedative treatment alone being admissible.

In favorable cases, however, in which inflammation is not present, large masses of œdematous tissue may be removed, with most brilliant results in the relief of the dyspnœa, the cough, and the dysphagia.

The operation by Krause's method is somewhat painful, even under cocaine, and for two days after its performance the patient is liable to undergo considerable discomfort. This is particularly the case in swallowing. By way of after-treatment the patient should be kept as quiet as possible, speaking should be interdicted, unirritating food should be carefully administered, and any tendency to inflammatory reaction checked by the swallowing of cracked ice, and by cold applications to the throat over the region of the larynx. Rest in bed is sometimes desirable. In cases where there is any tendency to laryngeal stenosis following Krause's operation the writer would suggest that dyspnœa may be avoided by the employment of intubation, as the introduction of an O'Dwyer tube for a few hours would probably succeed in relieving the difficulty.

Under the influence of the lactic acid healing is generally rapid, and the resulting cicatrix remarkably healthy in appearance. The most striking feature of the case is the absolute disappearance of the œdema, the interior of the larynx losing its swollen, sodden look, and the various parts of the organ appearing as in health.

Professor Krause states that he has operated in over one hundred cases. In none of these has he had bad results where no active inflammatory process was present. He has had but few failures; that is, cases in which some measure of relief was not afforded. A large majority of his patients have been helped. In a considerable number the results have been brilliant. In several instances he has effected a cure. By the word "cure" it is not meant that the lungs were restored to health, but that the larynx was relieved permanently, during the life of the patient, of all of the symptoms complained of before the treatment was undertaken, the length of time varying from four years to six months. When it is remembered that in every instance these were cases which almost inevitably run a course alike unfavorable to the comfort and the prospect of life of the patient, it cannot be denied that, if the statements and arguments of the advocates of Krause's method be true, we have in it a measure far in advance of those now in use, and one likely to be of incalculable benefit under most trying circumstances.

As to the testimony which others have offered concerning the value of Krause's method, it must be admitted that a number of the best authorities, so called, have met it with vigorous opposition. I am not aware, however, that this disapproval has been based upon carefully conducted experiments impartially undertaken to test the real merit of the operation, but believe that in the main it has been offered on purely theoretical grounds.

Thus, it is objected that the operation is difficult, requiring unusual technical skill on the part of the operator; that its application is painful and its effects attended with considerable suffering; that, in consequence of this, patients will refuse to submit to more than one application of it; and, finally, that it is absurd to state that tubercular laryngitis can be cured when the general condition, of which it is but a local expression, is sure sooner or later to destroy the patient.

That the operation requires considerable skill is true. Still it is satisfactorily performed by the assistants at Professor Krause's clinic, and it should be entirely within the reach of any specialist who is fairly proficient in intralaryngeal work. The operation is, in some cases, undoubtedly painful, even although done under the influence of cocaine. The amount of pain caused by it does not, however, seem excessive, even in the more severe cases, while the suffering which follows it for several days may be greatly relieved by the use of the proper remedies and applications. The healing process is so rapid that the painful stage quickly passes away, the suffering incident to the operation being inconsiderable in comparison with the radical and permanent relief afforded.

The good effects of the operation are speedily experienced by the patients, in consequence of which they do not object to necessary repetitions of it, but continue in

regular attendance at the clinic as long as may be required.

It is not claimed that by this or by any other treatment directed to the larynx a cure of general tuberculosis can be effected. It is perfectly fair, however, in referring to the local condition, to call that case cured in which all trace of active disease has disappeared from the larynx and all active symptoms referable to that organ have passed away, particularly where there is no recurrence of the local trouble during the remainder of the patient's life.

On the other hand, both Professor Krause and Dr. Heryng have been earnestly studying this subject for over five years, and they have now a considerable array of records to substantiate their assertions. What is even more important, others have taken the matter in hand. At the last meeting of the British Medical Association Mr. Charters J. Symonds, Assistant Surgeon in Guy's Hospital, presented a valuable contribution on the subject in an article giving an excellent *résumé* of these methods, and reporting in favorable terms their results in his own hands; while other contributions of greater or less interest have been appearing of late in the foreign journals. Since this paper was written, the article of Mr. Symons has appeared in print (October number of the *Journal of Laryngology and Rhinology*), and it is a pleasure to record that his experience is highly corroborative of that of Professor Krause. My own experience in the treatment of tubercular laryngitis by Krause's method is confined to the scraping of tuberculous ulcers and the use of lactic acid, and to what I have witnessed at his clinic in Berlin. In company with several friends, among them Dr. Thomas R. French, of Brooklyn, the clinic was visited last summer, and we were carefully instructed in all matters pertaining to the operation. Three patients, in all, were exhibited. All were young men. In one, a case of phthisis second stage, the larynx, which had been operated upon several weeks before, was perfectly healed and apparently in a healthy condition. The second was a case in which the treatment was but partially carried out. The patient, although he had been operated upon at several former sittings, made no objection whatever to returning to the clinic and submitting again. Both of these men expressed themselves as having been greatly relieved. The third case was that of a man in whom the lung symptoms were somewhat advanced. There was extensive œdema of the arytenoids, the posterior commissure of the larynx, and the false vocal bands, with some swelling of the epiglottis. The patient suffered from cough, dyspnœa, and dysphagia. The whole posterior part of the larynx was cleared at one sitting, *i.e.*, the œdema of the arytenoids, and the posterior commissure was removed. The operation was followed by application of the lactic acid as already described. Three days later the patient reported, having suffered considerably meanwhile. It was astonishing, however, to find, upon examining him, that the part of the larynx operated upon was apparently healed, the cavity of the larynx was much larger, and the swelling of the neighboring tissues considerably diminished.

The most surprising feature presented by these cases was, as has been said before, the remarkably natural appearance of the interior of the larynx after healing had taken place. Instead of the misshapen, pyriform swellings at the posterior part of the larynx, the normal shape of that region was restored, the arytenoids appearing as sharply defined as in health. The cavity of the larynx was spacious, the excursion of the vocal bands in inspiration perfect, and all of the characteristic deformities incident to tubercular laryngitis wanting. The explanation of this, it seems to me, is in the fact that œdema of the larynx is really a sero-purulent infiltration which is not especially affected by simple incision. The removal of a large portion of the surface of such an infiltration, however, and the subsequent treatment of the exposed tissue with lactic acid, produces extensive destruction of the diseased elements and a speedy elimination of the contained morbid products by that which remains, the healing process being quickly accomplished and resulting in a cicatrix apparently free from disease.

Mr. Symonds, in following the views of Professor Krause, very aptly suggests that our objects in operating are: "1. To relieve the cough and dysphagia, and so to bring about improvement in the general health, enabling the patients to swallow. 2. To diminish the liability to pulmonary affection. 3. To produce a more rapid recovery in those cases disposed to a spontaneous cure, much as is done in cases of tubercular disease of joints."

All of these objects, he believes, seem to have been attained by one or more of the methods described in this paper; and he also maintains that the results of such treatment fully justify our recommending the local or surgical treatment of laryngeal tubercle on lines similar to those employed for the same disease in other parts of the body.

Again agreeing with Krause, Symonds holds that the cases most suitable for operation are: "1. Those in which there is no evidence of pulmonary disease. 2. Those in which there is severe dysphagia and cough, with existing, but not rapidly advancing, pulmonary disease. 3. Those in which the pulmonary disease is early or chronic, as in these the latter may improve."

All the conditions present in tubercular laryngitis are amenable to treatment, but those most suitable are the tubercular tumor, that is, the localized formation of a mass of granulation tissue; next, the ulcer into which the lactic acid can be rubbed; and lastly, the infiltration and œdema, which may be removed by the curette. No one will be inclined to operate on patients with advanced pulmonary disease when there is hectic and rapid emaciation. . . . Granting the value of good hygienic surroundings which, of course, must not be lost sight of, for patients who cannot afford the luxury of a residence in the Adirondacks or in the South, where, no doubt, spontaneous recovery is greatly favored, much may be done even in unfavorable surroundings by local treatment. Speaking of the severe cases, Professor Krause says: "We must not despair even in these. I have observed cases in which, with all the unfavorable local and general symptoms, a careful and continuous local treatment was successful in curing the laryngeal disease. And I have seen others in which the disease was arrested, and, in comparison with the existing torments of hunger and inanition, a condition result which was at least bearable."

Symonds concludes that: "1. Tubercular disease of the larynx should be treated on the same lines as elsewhere, that is, by destroying it by an irritant, or removing it by erasion or curettement. 2. At present lactic acid is our best application. 3. Endo-laryngeal methods are sufficient to remove and treat the disease in a majority of cases."

Again, Luc (*Archives de Laryngologie, etc.*, August, 1890) points out that the considerations upon which the surgical treatment of tubercular laryngitis should be based are: *a*, the condition of the lungs and other organs; *b*, the precise stage of the laryngeal lesions; *c*, the personal character and social position of the patient.

He also believes that with proper hygienic care, and in suitably selected cases, good results can be obtained.

In the discussion which followed Symond's paper considerable difference of opinion prevailed. Those who objected did not appear to have put the question to decided practical test, while of those advocating it from the light of clinical experience, Mr. Lennox Browne gave it hearty support.

For myself, let it be distinctly understood that I make no claim with regard to the method, either for or against it. As a matter of fact, it is based upon the accepted scientific principles of the day; it promises results which have not been attained by any other means; it is being practically tested by many competent observers abroad. It has gained in favor, apparently, where it has been given fair trial. In view of its great possible value, and

of the interest which it has aroused in other lands, it has seemed important to bring it prominently before the profession, to urge its study, and provoke its discussion, and thus, lastly, to aid, if possible, in the final settlement of its position among the list of useful remedies for one of the most common and distressing maladies which afflict the human race.

WHAT WAS THE PHYSICAL CAUSE OF THE DEATH OF JESUS CHRIST?

By C. C. P. CLARK, M.D.,

OSWEGO, N. Y.

This question, the discussion of which has lately been revived in the *British Medical Journal* (?), and participated in in various other quarters, would seem to have been a puzzle both to the faculties of theology and medical science ever since biblical criticism has had a voice. And yet, if handled with frankness, it would not seem difficult of solution.

In the first place, it seems to be admitted on all hands that Jesus did not die from the immediate and natural, or ordinary, effect of his suspension on the cross. This method of punishment was very common among the Romans, Jews, and other nations of antiquity, and it is abundantly substantiated as a fact, in addition to its consistency with the established laws of human endurance, that the subject of it, when of ordinary health and strength, would survive his torture for from two to four or even five days. But Jesus was suspended but about as many hours, or not above six at the most. Accordingly it was that when at the ninth hour, or six o'clock P.M., Pilate was asked for his body, "he marvelled if he were already dead" (Mark xv. 44).

Nevertheless it has been the part, as it has been indeed the necessity, of orthodoxy to hold that when taken down from the cross by Joseph of Arimathea and laid away in the sepulchre (or recess in the rocky hillside), he was as veritably dead as the soldiers who were sent to break the legs of the crucified supposed him to be; and many ingenious explanations have been devised and argued to account for what, to those who stood by, must have been so strange and unexpected.

Without undertaking the task of setting forth and controverting these, and bearing in mind that the death of Jesus is nowhere represented by the evangelists or elsewhere as miraculous, or other than natural, let us examine the gospel narrative with an unprejudiced eye and see what honest inferences may be drawn therefrom.

And let us bear in mind, too, that the accounts there found are not only all that we have from which to make deductions, but that they are, at least excepting their miraculous or supernatural features, of unquestionable credibility in all essential particulars, differences of detail even lending support to the main story; the capture, the trial, the crucifixion, the interment, and the reappearance of Jesus among the living, are facts as assured to my mind as the taking of Jerusalem by Titus. No sufficient reason can be imagined for the invention of any of them, save only the resurrection; and that that really occurred so unexpectedly to all the disciples, the immediate and rapid spread of Christianity thereafter is alone sufficient evidence, since it is impossible to account for it in any other way. It was the "immortality (believed to be) brought to light through the Gospel" that alone gave that Gospel its enduring and conquering vitality, and is still both its chief support and the great stumbling-block of unbelievers.

What is spoken of by all the evangelists as the "giving up the ghost" by Jesus—it is uncertain how long before he was taken down from the cross—was undoubtedly partial or entire syncope from exhaustion, aided perhaps by the desolation that he felt when he found, or thought he found, himself forsaken by his God (Mark xv. 34); or it might be even that he affected a condition of insensibility in order to escape such further cruelties as the supplying his thirst with vinegar.

However this may be, we can well believe that when the soldiers came to finish the barbarous work, by breaking the legs of the victims, they found him in a condition which men even less ignorant, stupid, and careless than they most likely were, would easily and naturally take for actual death. For Jesus, it must be remembered, was already worn nigh to exhaustion with fasting and anxiety, to say nothing of his undoubted highly sensitive organization.

Here we come, in the Gospel according to John (xix. 32–37, and xx. 27) to a plain solution of the whole great mystery. Soldiers were sent by Pilate, at the request of the Jews, to break the legs of Jesus and the two thieves, in order that the ensuing "day of Preparation" might not be desecrated by their still hanging from the cross, and that they might be effectually disabled from escaping death. They practised this horrible feat of cruelty on the companions in misery of Jesus, but when they came to him they found, or supposed that they found, him to be already dead, and accordingly neglected to complete what anatomists know must have been a somewhat difficult job.

"But one of the soldiers with a spear pierced his side, and forthwith came thereout blood and water."

Now, there is but one part of the human anatomy, it need not to be argued, where the thrust of a spear would naturally be followed by such a phenomenon as this, and that is the region of the urinary bladder.

Moreover, while a wound like that would not immediately destroy life, and might even easily permit the sufferer to go or be conveyed about, and show himself from time to time for a few days, it would not, nevertheless, in view of the poor surgery of those times, and of the uncertain care, or even neglect, that a refugee would inevitably suffer, fail before any long time to prove mortal.

This, then, is the true story of the reappearance or resurrection of Jesus after his supposed death on the cross. Removed to the cool tomb by the tender hands of his friends, and placed in a horizontal position, he recovered, probably after some hours, from his state of syncope or collapse, and easily made his way to some selected refuge, leaving behind him the garniture of the grave which Mary, but not Simon Peter, took for angels clad in white raiment. Then he lingered out his few remaining days, securely concealed from his enemies, but revealed to we know not how many (in the disagreements of the evangelists) of his most trusted followers.

REPORT OF TWO CASES OF FRACTURE OF THE HEAD OF THE FIBULA.[1]

By A. J. McCOSH, M.D.,

NEW YORK.

Fractures of the head of the fibula are of uncommon occurrence. Very few cases have been reported, and the information which can be found about this rare accident in treatises on surgery, and indeed in most of the works on fractures, is comparatively meagre. Stimson, however, in his "Treatise of Fractures" (p. 586), pays no considerable attention to this injury and records seven cases, one having occurred in his own experience. Weir, in a valuable paper on this subject,[2] was unable to enumerate more than nine cases. I remember that his article was read at a meeting of the New York Surgical Society, and, with one exception, no other member was able to add to the list of cases.

In the reported cases this accident has been caused by either muscular action or by indirect violence. When due to muscular action, it has been produced by sudden and energetic contraction of the biceps femoris muscle;

[1] Reported at the Surgical Lecture of Academy of Medicine, October 13, 1890.

[2] New York Medical Journal, vol. xlvii., p. 561.

when due to indirect violence, it has been the result of forcible adduction of the leg. In the two cases which I present to-night we have an illustration of each of these methods.

While the result in each case is satisfactory, a marked difference exists now, as it did at the time of the injury, in the relation of the fragments to each other. In the one patient bony union has been obtained; in the other, the fragments are united by a fibrous band nearly one inch in length.

Case I.—H. D——, male, aged forty-six, hostler. On May 22, 1889, while in the act of lifting a horse's foot, the animal rolled over against the inside of his thigh, and as his leg slipped under the horse into a position of extreme adduction, he felt a pain and "something give way" on the outer side of his knee. He fell down, and was unable to rise. On examination, after admission into the Presbyterian Hospital, the smooth head of the fibula was not felt in its place, but at a point three-fourths of an inch above where it should be situated was distinctly felt a movable body of bony consistency, about the size of a hickory-nut. This mass could be easily grasped with the finger, was movable laterally, could be pushed upward for a short distance, but could not be made to descend toward the foot. It was directly attached to the tendon of the biceps femoris muscle. Below this was a depression of three-quarters of an inch, and then was encountered the upper end of a bone, somewhat square and angular to the touch, which on being traced downward proved to be the fibula. The patient was a thin man and the diagnosis was unmistakable. The injury consisted in a fracture of the upper end of the fibula, a fragment about three-quarters of an inch in length being drawn upward for a distance of one inch by the contracting force of the outer ham-string muscle. There was considerable swelling about the outer side of the knee joint, but no luxation could be produced. While the limb was straight an attempt was made to pull down the small upper fragment, but it was in vain. When the leg, however, was flexed, a certain approximation of the fragments was obtained. The limb was placed in a double inclined plane, the leg being flexed to about 30°, and the thigh slightly bent on the pelvis. A strip of adhesive plaster steadied and pulled down the upper fragment. In this position the distance between the fragments was estimated at about half an inch. Considerable pain was experienced on the outer side of the leg, and the position proved an uncomfortable one. There was no loss or impairment of sensation at any point on the leg or foot, neither was there any muscular paralysis present at any time. At the end of three weeks a plaster-of-Paris splint was applied, the leg being semi-flexed. At the end of the sixth week this was removed. At the end of three months the patient walked without a limp, and his injured limb was as useful as it ever had been. Since that time he has been following his trade without discomfort. At the present time there is a separation of three-quarters of an inch between the fragments, which seem to be united by a fibrous band. The upper fragment attached to the biceps muscle can be moved from side to side. There is no loss of sensation or motion.

Case II.—Male, aged thirty-one. In past years he had sustained on two occasions comminuted fractures of the left femur, and in consequence has had partial anchylosis of his knee-joint. On August 26, 1890, while descending some stairs he slipped and made a violent and sudden effort to recover himself. In doing so "he heard and felt something snap" on the outer side of his left knee. He fell, and was unable to get up. When brought to the Presbyterian Hospital, a fracture of the upper end of the fibula was found. The upper fragment was not more than one-half inch in length. When the limb was straight the separation between the two fragments was about a quarter of an inch; on flexing the leg and pressing the upper fragment inward toward the tibia bone crepitus was obtained and the fragments appeared to be in apposition. On removing pressure the lower end of the small upper fragment appeared to spring away from the joint, and in order to again bring the fractured surfaces together pressure inward had always to be made on the upper fragment. This evidently consisted merely of the styloid process of the fibula, which was drawn slightly upward by the biceps tendon, but it was probable that some of the ligaments which connected it with the tibia had not been completely severed, or else a greater separation of the fragments would have resulted. No paralysis of either sensation or motion was or has been present. The treatment was the same as in the other case, the leg being flexed on the thigh and a right-angled splint applied, a pad pressing the upper fragment into position. At the end of five weeks the splint was removed. The patient can now (seven weeks from time of injury) walk with the aid of a cane. Firm and apparently bony union has resulted. No separation between the fragments can be felt. The head of the fibula is increased in size and roughened, due to a moderate amount of callus which has formed about the fracture.

In neither of the patients just shown has there been loss or impairment of either sensation or motion in any part of the leg. Paralysis due to injury of the peroneal or external popliteal nerve is a serious complication which frequently results from this fracture. The injury consists either in complete division or in contusion of the nerve before it divides into the musculo-cutaneous and anterior tibial nerves. The result is a paralysis of the peroneal and anterior group of muscles, and a loss of sensation beginning about the middle of the outer aspect of the leg and extending downward over the dorsum of the foot. In the case of Dr. Merriam (reported by Weir), instead of loss of sensation there was marked hyperæsthesia combined with muscular prralysis. In the case which occurred in Dr. Weir's own experience he very successfully operated for the relief of this paralysis. This unfortunate accident took place in six out of the nine cases reported by this same writer, and resulted in more or less permanent impairment of the limb.

A CASE OF INSANITY APPARENTLY DUE TO PELVIC ABSCESS AND CURED BY SURGICAL TREATMENT.

By C. M. HAY, M.D.,

ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE NEW JERSEY STATE INSANE ASYLUM, MORRIS PLAINS, N. J.

The following case appears sufficiently interesting to warrant this notice of it:

Miss D. C——, aged twenty-three, single, and a hat-trimmer by occupation. Possessed fair education, but naturally of a low grade of intelligence. Admitted November 8, 1889. Family history unknown. Personal history prior to illness presented no circumstances bearing on the case. Her attacks began some two months prior to admission, with strange actions, dulness, stupor, and pain in left ovarian region. There was a progressive increase of these symptoms, and two weeks before coming here she was confined to bed in a mental condition alternating between "violent and threatening," and "quiet, seemingly demented," in the language of her physician. For her condition on admission here, and for the privilege of then seeing the case, I am indebted to my colleague, Dr. Elias Gorton, into whose service she was received. At that time her condition was as follows: A well-formed girl, above middle height, with healthy heart, lungs, and abdominal organs, except for an acceleration of the pulse beat, and gastric and intestinal indigestion. There was slight irregular fever, a yellowish-white, furred tongue, with prominent papillæ, and loss of appetite. The face wore a dull, anxious expression, there was great mental apathy and confusion of ideas, with a delusion that she had been pregnant for four months. The urine only contained a great excess of the earthy

phosphates, and was high-colored and lessened in amount. She gave a history of constipation. On examination the abdomen was a little full, and there was pain, tenderness, and tremor to deep pressure in the left iliac fossa. Examination proved her statement that she was pregnant to be a delusion, the uterus not being enlarged.

I next saw the case November 28, 1889, on which date she was admitted to the hospital wards, with a statement from Dr. Gorton that her symptoms had progressively become more marked, and that she had lost rapidly in strength and weight.

On admission to my wards a bimanual examination revealed a large indurated mass, occupying the left ovarian and iliac regions. The uterus was movable, and was much displaced to the right and slightly downward. The left tube and ovary could be outlined against the vaginal aspect of the tumor. Externally the swelling caused a decided fulness of the left iliac fossa and could be outlined by the fingers. It was not movable and fluctuation could not be obtained. The temperature varied from 99° to 102° F., and the pulse from 100 to 120 per minute, the impulse being irritable and weak. The woman had failed very much in flesh and strength. The memory appeared normal, and beyond dulness of intellect several examinations failed to reveal any defect of judgment, the imagination, or the special senses. Vision was normal. A certain indescribable air about the case led to repeated examinations of her mental condition, which, after her confidence had been fully obtained, revealed that she harbored a thoroughly systematized delusion, the main points of which were that her former physician, who attended her prior to her coming to this institution, was Jesus Christ, that if he were present he could cure her instantaneously. She described minutely his first visit, how she became impressed that he was a divine character, and how upon his once coming to her room she had recognized a halo about his head, and instantly realized that he was Jesus Christ. It may properly be mentioned here that the subject of this delusion is a venerable-looking doctor with white flowing hair and beard. In explaining her reasons for her belief she became animated to exaltation, but on ceasing speaking her ordinary air of melancholy and physical suffering returned.

She was placed upon a treatment of absolute rest, a light nutritious diet, a saline purgative in the morning, full doses of quinine, and moderate doses of opium, with local antisepsis and externally counter-irritation. This lowered the fever and relieved pain, so that for some days the patient seemed to be improving, but on December 9th she grew worse, and failed steadily until the 14th, when a severe chill occurred, followed by high irregular fever, sweats, and marked cachexia.

Examination now revealed some enlargement of the tumor with imperfect fluctuation. On the 16th, with the assistance of Dr. L. L. Mial, I evacuated the abscess by an oblique lateral incision through the abdominal wall. Upon introducing the hand into the cavity the left tube and ovary could be felt a little enlarged. The upper wall of the abscess was extremely thin, and the intestines could be plainly felt through it. The contents of the abscess consisted of purulent pus with shreds of lymph. The upper wall was carefully curetted with the finger-nail, a considerable quantity of indolent fungoid granulations being removed. The cavity was then cleansed and two large rubber tubes left in, one directed down into the pelvis, and the other upward toward the intestines, and an ordinary dressing applied. On the third day an erosion into the intestine occurred and considerable fecal matter was discharged in the dressings. The case was then dressed twice a day, being thoroughly cleansed each time by irrigation with a medium-strength solution of the permanganate of potassium. In ten days the fæces were normally passed and the abscess discharged healthy pus. The tubes were gradually shortened and removed in a month, and the patient was practically well on February 15th—only a small fistulous tract in the abdominal wall remaining, which healed kindly in a few weeks. Under tonics and moderate exercise she rapidly gained flesh, and on March 24th was perfectly well. Menstruation returned regularly, it having been absent for four months prior to operation. On this date she appeared entirely rational, but when questioned concerning her delusion, it was still present, but she was not enthusiastic over it. Her general mental condition was excellent, and no one would have discovered any mental trouble in her, except informed regarding her secret delusion.

July 19, 1890, she is a picture of health. No return of local symptoms; states she only dimly remembers events up to time of operation, and that the greater part of the time previous to it is a total blank. Frankly admits the falsity of her delusion respecting her physician. The exact time of its disappearance cannot be ascertained, but it was between March 24, 1890, and July 19, 1890. She was kept under observation until October 1890, and then discharged wholly well, mentally and physically.

Remarks.—In this case an elaborately systematized single delusion, which prior to operation was firmly fixed, after it slowly faded and finally disappeared. From the history of the case it will also be noted that the delusional belief arose gradually during the invasion of her pelvic trouble, and that it was attended by other evidences of insanity. The abscess itself, in the absence of tubo-ovarian disease, can only be attributed to an indefinite traumatism received a short time prior to her illness. Coincidentally with its development the mental symptoms appeared, and there were, at first, mental confusion with stupor and apathy, and a condition of semi-dementia with a few maniacal outbreaks. In two weeks these symptoms passed away, leaving her dull and depressed, and with a few simple delusions. One of these delusions, viz., that her physician was Jesus Christ, etc., developed and became thoroughly systematized and fixed, while the others, including the belief that she was pregnant, etc., faded away; so that at the time of the operation she was practically sane, with the exception of this single complex delusion. From the character of this delusion, and the very positive manner in which she reasoned to prove its reality, it was feared that it was only an initiative symptom of a chronic mental degeneration. After two months, however, her general improvement and the degree to which the other mental faculties gained power, warranted the hope of her final recovery, and the case was watched with considerable interest, with the gratifying result already described.

The mental symptoms in this case corresponded to none of the ordinary forms of insanity, but were, as will be seen from the above account, distinctly atypical.

There has been no similar case admitted since my residence here, in a total of over four hundred admissions.

Clinical Department.

ERYTHROMELALGIA.

By A. V. WENDEL, M.D.,

NEWARK, N. J.

In the latter part of last July I was called to Mrs. G——, and obtained the following history: She was sixty-two years of age, had borne four children, and by occupation a nurse. Her parentage had been healthy, father dying at ninety-six from an accident. Her own health had always been good up to last April. At this time she was nursing a case of puerperal septicæmia, and a number of times daily had to wring out cloths dipped in hot carbolic acid solution. After doing this for several days Mrs. G—— noticed her feet to be very painful, and on examination blue and swollen on the anterior portion. These symptoms became so severe as to oblige the patient to give up her profession and take to bed. The pain was excruciating, especially at night and on pressure, the attacks coming on paroxysmally.

When I was consulted I found her much emaciated, with atheromatous arteries, obstinate constipation, feet presenting, over the anterior and lateral aspects, especially on the plantar surfaces, irregular bluish purple spots, very sensitive, and sweating freely. Urinalysis gave negative results.

The treatment consisted of a ferruginous tonic, the usual hygienic measures, and cold affusions locally; while the general condition improved the local did not. The local application of belladonna, hot water, etc., failed. Electricity only aggravated it. I then decided to put her on arsenic—the liq. acidi arseniosi—directing it to be pushed until physiological symptoms became manifest.

After several days of this treatment the patient began to improve, and six days after walked around the block with ordinary shoes, being the first time in months that she had been able to tolerate any covering on her feet. Improvement went on so rapidly that a week ago I stopped the arsenic, no unfavorable symptoms having appeared to this time. Whether the carbolic acid may be considered in the relation of cause and effect, or simply coincident, I am unable to say. The failure of all other remedies and the favorable influence of arsenic in this case, certainly warrants a faithful trial in this painful affection.

134 Newton Street.

Progress of Medical Science.

Embryology.—At the Leeds meeting of the British Association for the Advancement of Science, Professor Milnes Marshall, in his presidential address to the Biological Section, said that embryology had thriven mightily of late years; but the watching of all the processes of development was of trifling account compared with the great generalization, which showed that the development of animals had a far higher meaning. The phases through which an animal passed in its own development were no accidental freaks, but represented more or less closely, in more or less modified manner, the successive ancestral stages through which the present condition had been acquired. Evolution told us that each animal had had a pedigree in the past; embryology revealed to us this ancestry, because every animal in its own development repeated this history. Such was the recapitulation theory. This had been hinted at by Agassiz, suggested more directly by von Baer, but first clearly enunciated by Fritz Müller; it had since been elaborated by many, notably by Balfour and by Ernst Haeckel. "Natural selection" explained the preservation of useful variations, but it did not account for the formation and preservation of useless organs. "Recapitulation" solved the problem at once by showing that these organs, though now useless, must have been of functional value to the ancestors of their present possessors, and that their appearance in existing forms was due to repetition of ancestral characters. Man himself presented many such features. The existence in the human adult of ear muscles which he did not use, of gill clefts in the embryo that never possessed functional importance, furnished suggestions of past history identical in the lesson they gave with that which the linguist found in the retention of a silent consonant in some words. The principle of degeneration, also, should not be overlooked. Professor Marshall emphasized the importance of Kleinenberg's theory as to the development of new organs, but said it was yet too early to realize the full significance of it. Embryology, though, could not provide an immediate or complete answer to the great riddle of life; it was a means, not an end.

The Treatment of Abdominal Hydatids.—Although many people hold that Trousseau's method accomplishes the safe removal of hydatids from the abdomen, yet actual practice proves otherwise. Septic peritonitis, as indicated by abdominal distention and elevated temperature, is found in many cases to follow the introduction of pins. Whenever pins are introduced with the view of causing adhesions, that object can be achieved in two ways only, either by the presence of germs on the pins that set up adhesive processes, or else by a leakage of fluid of the same properties. Perfectly sterile pins cannot give rise to adhesions. On the other hand, by introducing septic pins, or by a leakage of irritative fluid, a peritonitis will ensue, the control of which is out of the hands of the operator. The aseptic era, however, has given us, in von Volkmann's method, the ideal execution of Trousseau's original plan. It is now an established fact that there is no more danger in opening the peritoneal cavity than in cutting off a finger; hence that operation may be used for purposes of diagnosis. These facts being granted, the writer asks why uncertain, or even dangerous, methods should be adopted for the production of adhesions, when we are able to secure them by an open and scientific operation. It has been maintained that Trousseau's method is easily performed, and therefore best suited to the greater number of operators. The writer asserts that he can perform von Volkmann's method in less time than that occupied in introducing the needles by the other plan. Great operative skill is not necessary. Anatomical knowledge and strict asepsis are the two indispensable requirements. In following von Volkmann's method the operator has the great advantage of being able to see what he is doing. The abdominal cavity is freely opened, and the cyst extensively exposed. A week later it is incised, and there being by that time firm adhesion to the abdominal parietes, peritonitis is rendered impossible. Six successful cases are reported, in none of which the temperature reached 100° F., nor was there any sign of peritonitis. In one case there was a cyst of left lung, which was reached by resection of a rib, followed by pneumothorax. The writer had twice to make a way through the substance of the liver, when he used Paquelin's cautery, and found no difficulty. The track is kept easily open, and the discharge of bile is harmless, and soon disappears. Dr. Ross has opened two cysts situated on the convexity of the liver, one from above, and the other from below the diaphragm. He prefers the higher operation. In opening below the diaphragm, the latter is apt to block the tube, and to greatly interfere with drainage.—*The London Medical Recorder.*

Treatment of Enlarged Bursæ and Ganglia.—Mr. Bond states that he is strongly in favor of the treatment of enlarged bursæ in the neighborhood of large joints by the radical method of excision of the whole or a large part of the cyst-wall. In dealing with these swellings in the popliteal space, the incision must be made well down to the cyst-wall before beginning any dissection; if this be done, and the cyst well defined while tense and before it is opened, it can be isolated without difficulty. It is then best to lay it open, and ascertain from within what extensions and communications it has; these must be dealt with, and then as much of the cyst-wall removed as possible. In dressing the wound, pressure should be applied with wool-dressing, and the limb bandaged in a semiflexed position, so that the skin and soft parts fall together, and a tightly stretched scar is avoided. The same method may be extended to the enlarged bursæ over the olecranon and patella. The treatment of the swellings in the sheaths of the tendons in relation to the wrist-joint is next discussed. Those simple ganglia which are too large to rupture are best treated by excision. An incision is made over the swelling, which is isolated as far as possible; it is then laid open and its prolongations defined. As much of the cyst-wall as can be isolated is then cut away, and the posterior portion lying over the wrist joint is left. As a rule, the wound heals by first intention, without any adhesion of the tendons. In cases of compound ganglia the operation is sometimes very complicated, the tendons being studded over with a velvety membrane and vascular fringes, like the lining membrane of the cyst-walls. In these cases the tendons must

be picked up separately, and systematically cleaned, one by one; when this is done, the wound should be stitched up, and, as a rule, good movement is obtained in a short time.—*The Practitioner.*

Bacteriological Researches as to the Nature of Ozæna.—Dr. Marano conducted his researches in the laboratory directed by Professor de Renzi, at Naples. The secretions examined were taken from ten patients suffering from ozæna, in the clinic of Professor Massei (the London *Medical Recorder*). Microscopical examination of dried specimens showed, among detritus of mucus and pus cells, small bacteria, a few longish bacilli, and many micrococci of various sizes. Among them, however, was constantly to be found a short, thick bacillus, almost always in the form of diplococcus, surrounded by a peripheral halo-like capsule. Cultivation experiments always yielded, with other variable forms, a thick bacillus, almost always in the form of diplococcus and encapsuled, and perfectly like that observed in the dry preparations. This rhinobacillus is identical with that described by Loewenberg, who, however, owing to defective methods, did not find the bacillus encapsuled. One of the characters which distinguishes it from other capsuled microbes is a clear zone of whitish color which appears toward the extremities and toward the middle. The bacilli are disposed variously in chains and masses. All the usual mediums are favorable for culture of this microbe, especially gelatine, and the cultures present distinctive characters. Control-researches were performed with the object of seeing if this bacillus was constant in ozæna alone, or if it accompanied other catarrhal and inflammatory affections of the nasal passages. He examined the secretions from individuals affected with chronic catarrh, and with dry and atrophic forms; he examined, also, normal mucus, and mucus from a case of chronic atrophic rhinitis consecutive to ozæna, as well as from a case of fetid rhinitis consecutive to myxomatous tumors. The result was always negative. The capsuled bacillus of ozæna was always absent. Other questions remain to be solved, such as whether the bacillus is the causative agent of the pathognomonic fetidity, whether it is the cause of the disease, and, lastly, whether inoculations can produce the disease in all its phases. As to the fetor, M. Marano never found it in pure cultures, but in direct inoculations about the eighth or ninth day a stinking odor developed, which, however, was not that of ozæna. Suspecting that the fetor was produced, not by the sole action of the capsuled bacillus, but by its influence combined with that of other normal micro-organisms of the nose, he inoculated a pure culture of capsuled bacilli with a microbe of the nature of staphylococcus. After two days a fetid odor was present, not identical, however, with that of ozæna, but resembling it. As bearing on the other questions, M. Marano states that inoculations made on dogs and rabbits gave a negative result; he, however, hopes to make further experiments on this point.

The Hæmatozoa of Malarial Fevers.—Dr. Fajarnes gives a condensed statement of the existing state of opinion among the microbiologists in reference to the parasitic origin of intermittent fever. He observes that the conclusions flowing from Laveran's investigations were accepted by some and combatted by many others, while the views of Klebs and Tomasi-Crudeli had currency for a time, during which their bacillus was described as the specific germ of paludal fevers. The discovery of hæmatoblasts, with or without pigment, in the blood of those suffering from ague, which was made by Marchiafava and Celli, seems sufficient to distinguish the malady, especially as their experiments have been confirmed and completed by Golgi, Mechnikov, Councilman, and other investigators. Klebs and other observers in the same field would not admit this. They held that these microbes are not living organisms, but different forms of hyaline degeneration of the red corpuscles of the blood, which had, indeed, been artificially produced in animals by Mosso and Schiavuzzy. Golgi, on his part, showed that the bacillus of Schiavuzzy is not a morbid product at all, and that it has nothing to do with paludal fever. Gentsinsky sustains that the organism described by Laveran (hæmatoficus malaricus) is the cause of ague. Ferran, on the other hand, affirms that he can nowhere find Laveran's parasite. Laveran has published a *résumé* of the works on the subject published by him during the last ten years, from which we take the description of the different microbes described in the blood of those affected with malarial fever. 1. Spherical bodies. These are the commonest. They are formed of a transparent hyaline substance. Their diameter varies from 1 to 8 mm. of mm. They exhibit amœboid movements. Laveran met them 389 times in 432 ague patients. 2. Movable filaments. Whip-like bodies. They are transparent, very fine, from 21 to 28 mm. of mm. in length. They exhibit lively and varied movements, glide along in the blood, and are sometimes united by one of their extremities to a spherical body. They are formed from the spherical bodies, and each of them may have two or three filaments, disposed without any regularity or symmetry. Bouchard, Strauss, and Laveran consider the flagella as characteristic of paludal fever. 3. Crescent-shaped bodies. Colorless and transparent, with black pigment granules in the middle, from 8 to 9 mm. of mm. in length, and 2 in breath. 4. Hyaline bodies. Motionless, irregular in shape, and with pigment. He considers them to be bad forms of the spherical bodies. 5. Tassel-shaped bodies. Spherical in shape, with pigment in the middle and segmented in a regular manner. Laveran assigns to them a secondary place, but Golgi gives much importance to them. Leucocytes of various forms are also observed in the blood, and they are supposed to represent different phases in the evolution of the same parasite. Laveran found in the blood of 432 patients affected with paludal fever:

Spherical bodies alone in	31
Spherical bodies and flagellæ in	33
Crescentic bodies alone in	43
Spherical, crescentic, and flagelliform bodies in	59
Spherical and crescentic bodies in	266

Most of those who have studied the question, including Dr. Fajarnes, have accepted Laveran's conclusions. Since 1870, ten different species of microbe have been observed and brought forward by different observers as the essential cause of malarial fever, but the repetition of the names assigned to these organisms would scarcely be instructive to the reader.—*The London Medical Recorder.*

Palatable Castor-Oil Mixture.—In the following preparation of castor-oil the disagreeable taste of the oil is replaced by a pleasant flavor of almonds:

℞. Castor-oil	30 parts.
Bitter almonds	2 "
Sugar	30 "
Gum tragacanth	½ part.
Orange-flower water	10 parts.
Water	120 "

Mix.

The only drawback to this mixture is that it requires a good deal of it for a dose, a teaspoonful of the oil being contained in about five teaspoonfuls of the mixture.]

It is said that the Practice of Drinking Cologne is becoming very common in Europe and in this country, and, as an indication of this, that the sale of the perfume has increased greatly of late years. Women are more addicted to the habit than men, and a writer in the *Quarterly Journal of Inebriety* says that the presence of obscure and complex nervous disorders in a woman who uses cologne externally should always suggest the possibility of its internal use.

MEDICAL RECORD:

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place

New York, November 15, 1890.

KOCH'S "CURE" FOR CONSUMPTION.

As we write, the daily papers are printing, with every issue, some fresh news of the wonderful, and as yet secret, "cure" for consumption discovered by Dr. Robert Koch. The interest in it is natural and intense. In this country there are some two hundred thousand sufferers from this fell disease, and in Europe and other parts of the world a still greater army of victims are hopefully looking for some cure, or patiently awaiting the end.

The expectations aroused by the numerous and mysterious reports that are issued from Berlin must be very great. It is well, therefore, to consider how much can be in fact realized by the announced "cure." Of it we know at least this, that it is a germicide, and that its action depends upon its destroying the vitality or power of growth of the tubercle bacilli. If this is the case, it is a remedy that must have various limitations to its usefulness. Phthisis is, in most cases, in its inception an infectious bacillary disease. But after lung tissue is once well invaded, and necrotic and inflammatory processes set in, the infection is a mixed one, and pyogenic organics are largely in control. No agent which simply destroys tubercle bacilli can, therefore, seriously modify the phthisical process. Germicides cannot cure phthisis in its second and third stages.

We are confident that Dr. Koch will not claim this for his "cure." Already it is stated that cases of lupus, of tubercular joints, and of phthisis in the first stage have been cured. But all these forms of tuberculosis can already be relieved by surgical and hygienic measures at our disposal. It remains to be seen, therefore, whether Koch has really supplied us anything which will carry the treatment of tuberculosis any further than it already has been brought.

One thing further, perhaps, he has achieved, viz., a method of prevention for those susceptible or exposed to the disease. This may be a gain, although the prevention of phthisis in individual cases is almost always possible if proper care is taken.

THE TREATMENT OF A NATIONAL STERILITY.

THE discussion in France over the subject of its decreasing birth-rate and slight increase in population, has brought up a great many questions which are of medical interest. In 1888 there were 882,639 births and 794,933 deaths. The ratio of births has fallen from 30 per 1,000 in the early years of the century to 23 per 1,000. The number of marriages has fallen to 7.1 per 1,000, and the number of births to each family has fallen to three. Divorces are increasing in frequency, especially among the educated classes, while the tendency is for marriages to take place later in life. The death-rate alone makes a favorable showing, it being less than in previous years.

The Académie de Médicine has taken up the study of this matter, and M. Lequean has proposed to it certain therapeutical measures for alleviating the national sterility.

The tendency to late marriages, he thinks, ought to be opposed, for the reason that by such delay the man may get syphilis and become sterile, and the woman's period of fecundity is shortened. There are 127,143 religious celibates in France. If these were married, the birth-rate would be increased from 23.09 to 23.11 per 1,000. The law of primogeniture and the expenses and formalities of the marriage contract tend to lessen the number of married people.

Prostitution and syphilis are thought to be two of the most important factors in causing a low birth-rate.

The proportion of sterile marriages in France is estimated to be 13 per 100, while the normal rate, or at least the average rate, in other countries is about 10 or 12 per 100.

The mortality in France is not great, but can be reduced.

M. Lequean recommends specifically, as measures to increase natality, protection of young women, by raising the responsible age to twenty-one, and making the father of an illegitimate child responsible for its care.

Legislation favoring marriage, by increasing the taxes and military duties of celibates, is advised. The regulation of prostitution, and especially the prompt and general treatment of venereal maladies, is considered also as of the greatest importance.

It may be that French legislators can devise laws which will help a little to increase the national birth-rate, but it seems a very desperate task; for the causes of the decline of population in France are most likely deep-rooted and dependent upon an inherent defect in race quite as much as upon bad artificial conditions. There is hardly a single factor mentioned by Lequean as a cause of the low birth-rate of France which does not exist in other European countries whose birth-rate is a normal one.

METHYLENE AS AN ANÆSTHETIC.

DESPITE the fact that so eminent a surgeon as Sir T. Spencer Wells uses methylene as an anæsthetic, and has continued to advocate its use for twenty years, very few have followed his example. This is because the statistics of mortality from this anæsthetic apparently show it to be considerably more dangerous than ether.

A recent fatal case at the Plymouth Hospital has called out a letter from Sir Spencer, in which he states that this and other accidents have been due to improper administration. He says: "I have never, either in hospital or private practice, since I began to operate in 1870 under methy-

lene, ever seen anything approaching to danger under its influence, nor have I had a moment's uneasiness or apprehension such as I have repeatedly suffered during the administration of chloroform, ether, the A. C. E. mixture, laughing-gas followed by ether, or the mixtures of chloroform and alcohol which some have supposed to be identical with, or substitutes for, methylene. And it is very seldom that in the most prolonged operations—say, for an hour—more than from six to eight drachms of methylene are used; while I have repeatedly found that in operations of fifteen or twenty minutes, not more than from two to three drachms have been evaporated."

Sir Spencer uses the Junker inhaler, and insists that the anæsthetic must be given freely diluted with air.

THE EDISON TREATMENT OF GOUTY CONCRETIONS.

Mr. Edison has before this stepped into the arduous field of therapeutics, bearing with him some kind of a complicated liniment, which speedily fell into disuse.

Now the distinguished electrician is making some experiments in the treatment of gouty concretions. The idea which Mr. Edison had worked out is that by using strong electrical currents these concretions can be absorbed and carried off. After making some tests with membranes and solutions, he tried (*Therapeutic Gazette*) whether a healthy man, after being subjected to such a course of treatment as a patient suffering from concretions might be expected to undergo, would not give indications of the absorption of lithium in his excretions. In October, 1889, J. D——, an active, healthy laborer, aged twenty, and of one hundred and forty pounds weight, was operated upon in his laboratory. He sat in a chair, and kept his hands immersed to the wrists in glass jars, one containing a solution of two per cent. lithium chloride with a platinum electrode, and the other containing a solution of common salt with the negative electrode. The current passed through him was four milliampères, which was as much as he could conveniently stand. This treatment was continued for about two hours daily during one week, the total time of application amounting to eleven hours. His urine was collected during that week, and tests were then applied to it.

Traces of lithium were found.

The next experiment was made upon a man, aged seventy-three, who had suffered from gout for ten years, and all of whose joints except the knees were involved. A current of about twenty milliampères was passed through a jar containing an aqueous solution of lithium chloride, density 1.08, in which the patient immersed his left hand up to the wrist. His right hand was similarly immersed in a solution of common salt.

The current was given four hours a day for six consecutive days. At the end of this time the size of one of the joints of the little finger had diminished from 8.6 ctm. to 8.2 and later to 8 ctm. There was also some relief of pain.

It seems to be thought from this that an actual absorption of concretion took place. It might, however, easily be that the slight reduction in swelling was due to absorption of inflammatory products. It has long been known that electrical currents will apparently do this.

Mr. Edison's experiments, therefore, seem to us to be very inconclusive; they are interesting, however, especially in showing that an aged man can take a current of twenty milliampères for four hours daily, and feel no especial effects therefrom.

A REFLECTION UPON DOCTORS, MORTALITY, AND ATHLETICS.

Our esteemed and reflective contemporary, *Life*, has been engaged of late in certain contemplations upon mortality and death.

In re the subject of sickness, it wonders why Mr. Richard Croker, whom the doctors pronounced incurable, incontinently got well; and it deduces some conclusions unfavorable to the certainties of medical science. Perhaps its reflections are not altogether without justice, although medical men are, we think, particularly careful in giving positive unfavorable prognoses. When given, they are generally correct, for most fatal and incurable diseases are readily recognized. We must believe that in the case of the eminent statesman above referred to there is a mistake. Either the doctors did not in fact say he was incurable, or else his time will come later. We trust Mr. Croker will not forget what he owes to the science of prognostics and the stability of professional reputation.

But *Life* is also puzzled over the careers of the late Cardinal Newman and John Boyle O'Reilly. The former, a frail, slight man of infirm constitution, but despite this he lived to a very advanced age; the latter was a man of splendid physique, who kept his system in training by physical exercise, athletic sports, and followed all the suggestions of modern physical culture. Yet he died in the prime of life. Shall we not, then, live quiet, ascetic lives, ignoring the body and cultivating the spirit? or shall we cultivate both body and mind? The latter course is the one so much commended to-day; yet it is not a sure passport to longevity, as many cases prove. In fact, the brain-worker is better if he lives a regular, temperate life, and pays no attention to the development of his muscles. A little walk, some fresh air, and sound sleep are all he needs. Some people, to be sure, can be athletes and do brain work also, but it is not the rule. A sound mind should have a sound body, but it does not need herculean muscles. The best athletic work is done by growing boys and adolescents, who have an extra supply of vitality. When they have matured, and undertaken the responsible work of life, they speedily drop out of the championships. And the lesson we would draw from the opposite cases brought up by *Life* is, that athletics are not needed by brain-workers, and will, if carried to excess, shorten life rather than lengthen it.

THE PREVENTION OF DIPHTHERIA AND SCARLET FEVER.

There are nearly two thousand deaths from diphtheria, and nearly as many from scarlet fever, in this city every year. The figures, to be sure, have fallen below this occasionally, but the number is always high. Three or four thousand deaths means, at a very low estimate, twenty or thirty thousand cases of sickness from these

diseases. The cost of such sickness, directly and indirectly, runs up into the millions.

People do not yet appreciate the economics of preventive medicine, but it will some time come to them.

Meanwhile physicians and sanitarians are working out the problem. Dr. Seibert, in an article on "The Prevention of Diphtheria and Scarlatina," makes a suggestion which will appeal rather directly to the self-interest of the medical profession.

Speaking of schools as centres of infection, he says: "Nothing but radical measures will bring about a change in preventing the spread of the disease in the schools, and he recommended that the throats of all school children be examined by a physician every day, the children to use their own fingers as a tongue depressor, and when the physician saw anything suspicious or out of the way, though not diphtheria, send the child home with the information that it was sick, and to send for the family physician. This work would cost the city about one hundred thousand dollars a year, paying each of three hundred physicians about three hundred dollars a year."

Three hundred places at three hundred dollars a year would be a fine plum for some of our city's political machines to dispose of. No doubt the proposition to establish such offices would be met with a shock of horror by the good citizens of the town, who would see in it only another public crib for the especial delectation of medical men. If these officers, however, succeeded in stamping out diphtheria and scarlet fever, the city would save and the doctors would lose hundreds of thousands of dollars. For the existence of twenty thousand cases of these zymotic fevers means large sums of money to the medical profession.

Yet the doctors have always energetically initiated and loyally supported all measures for the prevention of disease, and they would join, no doubt, in promoting the one here suggested if it were considered feasible and effective.

THE TEMPTATION OF JOHNS HOPKINS.

It is announced that the committee of ladies who resolved to raise $100,000 and give it to Johns Hopkins University for the purpose of founding a medical college to which women would be admitted, have succeeded in their purpose.

In tendering the money conditionally to the trustees the committee say: "There is little doubt that a sufficient number of women ought to be educated and trained in such manner as to be fully able to care for sick women who may wish or ought to be treated by women. We have devoted ourselves to the furtherance of this object. We have reason to hope that a university which proposes to found a medical school intended to teach advanced methods in the treatment of those diseases which afflict mankind will not refuse to women the opportunity of learning such methods."

The trustees, it is announced, have accepted the gift, and hereafter Johns Hopkins is to be a bi-sexual institution so far as its medical department is concerned.

This action of the trustees, it is believed by many, will seriously impair the prestige and limit the usefulness of the university's medical school. Much was expected of it at one time, but the profession will no longer turn kindly to an institution which sells its privileges for the ineffective sum of $100,000. The school was expected to start to work with a high-class equipment which would draw to it the best educated and most ambitious students. This class of men, however, in surveying the field, will now find that there are half a dozen other medical colleges equally well, or better equipped, in which they can pursue their studies without the disillusioning propinquity of lady medicals; and they will choose such places. For, however much man may esteem and honor woman he prefers to pursue anatomical and pathological studies alone.

The medical education of women has thriven but in independent institutions, as the prosperity of the colleges in New York, Philadelphia, and Chicago shows.

The action of the Johns Hopkins trustees may be lauded as evidence of broad and liberal views; as a matter of fact it is, we fancy, the result largely of the persistent nagging of some of the estimable and well-meaning ladies of Baltimore. The action was not needed in the interests of the medical education of women; for the sum of $100,000 given to the Women's College of this city, or of Philadelphia, would have provided much more effectively for this purpose. Thus the donation to the Baltimore school lowers the school without elevating the woman; for Baltimore cannot supply the clinical opportunities offered to women in the larger cities. And $100,000 is but a bagatelle in running a great medical school with male and female compartments.

A DIRECTORY FOR NURSES.

A correspondent of our melodious contemporary, *The Nightingale*, sends to it a letter which calls up a matter that ought to interest the profession of this city. She says:

"I am not personally interested in the opening of a directory for nurses in New York, but only as having been for nearly three years connected with the Brooklyn Directory, and knowing how very beneficial it would be to nurses, physicians, and the public. I think it a very serious drawback that in New York the physician should be so often called to hunt up a nurse when his time may be of great value and a life may depend upon his presence in the sick room. Again, the present directories are unfair to the nurse. They charge $3 for registering, and then ten to fifteen per cent. of your earnings. No woman will pay this enormous percentage if she can possibly get work without it. Physicians do not, I think, as a rule, know how large this fee is. I have spoken with a number of prominent physicians, and they say that a central directory would be a great convenience, and would undoubtedly succeed.

"The Brooklyn directory was founded some six years ago, by an appropriation of $500 by the Brooklyn Medical Society. There are now some 265 nurses on its roll, and it is self-supporting and a complete success. Nurses pay a $5 fee the first year, and $2 yearly afterward. Now in a city like New York the expenses of finding a nurse would be greater and the fee would require to be larger, but still it need not be burdensome."

There are, we believe, at least three bureaus for nurses

in the city conducted under private auspices. Some objections to them are referred to by the correspondent.

Some difficulty is undoubtedly at times experienced by physicians in getting nurses promptly.

A nurses' directory has been successfully conducted in Philadelphia in connection with the College of Physicians and Surgeons. Perhaps in this city the County Medical Society or the Academy of Medicine might take hold of the matter.

News of the Week.

A Hospital Unpleasantness.—Dr. Charles Meigs Wilson has resigned the position of chief physician of the Philadelphia Lying-in Charity.

Death of Dr. A. B. Carpenter.—Dr. Arthur B. Carpenter, of Cleveland, O., died suddenly at his residence, October 15th, at the age of thirty-seven, of fatty degeneration of the heart. Up to within three hours of his death he appeared in robust health. Dr. Carpenter was eminently a self-made man, of commanding presence and genial address; he had attained a large practice in the domain of gynecology, to which subject he had contributed many valuable articles. He was an active worker and took a prominent position in the local and national medical societies. In his untimely death the medical profession of Ohio has lost a most valuable member. According to an expressed wish, his remains were cremated at Buffalo.

Reports at the Academy on the International Congress.—The meeting of the Academy of November 6th was devoted to the reading of reports on the Berlin Congress. Dr. A. Jacobi, Chairman of the American Delegation, read an introductory which appears in this issue. The other reports were from members of the Academy who had attended the various sections: Section on Internal Medicine, by Dr. F. P. Kinnicutt; on Surgery, by Dr. Robert Abbe; on Ophthalmology, by Dr. Herman Knapp; on Laryngology, by Dr. F. H. Bosworth; on Neurology, by Dr. M. A. Starr; on Dermatology, by Dr. A. R. Robinson; on Orthopædics, by Dr. N. M. Shaffer; on Gynecology, by Dr. H. J. Boldt. Dr. A. Caillé said that, owing to the lateness of the hour, he preferred to present his report on pediatrics to the Section on Pediatrics. The reporters sought to give, in a very condensed form, the scientific facts of greatest interest presented at their respective sections.

Section on Genito-urinary Surgery of the Academy.—At the same meeting, November 6th, the Academy voted in favor of establishing a Section on Genito-urinary Surgery.

The New York Academy of Medicine.—The new building of the Academy, at 17 West Forty-third Street, which has been in process of construction for the past eighteen months, is now completed, and is to be opened with appropriate ceremonies and a general reception on November 20th. The anniversary address will be delivered by Dr. Edward L. Keyes, on "The Academy of Medicine." Dr. Loomis will give an address of welcome. Drs. Billings, of Washington, Weir Mitchell, of Philadelphia, and Fitz, of Boston, will express the congratulations of other cities at the completion of the building. Dr. Jacobi will give some account of the library of the Academy, which is now the most complete working medical library in the country after that of the Surgeon General, at Washington. On behalf of the many generous citizens, outside of the profession, who have contributed to the erection of the edifice, Mr. D. Willis James will speak, his subject being "The Influence of Scientific Associations upon Great Cities." The exercises will be concluded by remarks from Dr. Fordyce Barker. Invitations have been extended to a large number of distinguished persons, and it is expected that the reception will prove a memorable occasion in the history of the Academy. Admission will be by card only.

Dr. F. G. Test has been appointed superintendent of the asylum for the incurable insane at Hastings, Neb. Dr. Test has been the assistant superintendent for some time, and the acting superintendent since the resignation of Dr. Stone.

The New York Obstetrical Society.—At the annual meeting of the New York Obstetrical Society, held October 21, 1890, the following officers were elected: *President*, Dr. Joseph E. Janvrin; *First Vice-President*, Dr. Henry C. Coe; *Second Vice-President*, Dr. Robert A. Murray; *Recording Secretary*, Dr. Arthur M. Jacobus; *Assistant Secretary*, Dr. James R. Goffe; *Corresponding Secretary*, Dr. Augustus H. Buckmaster; *Treasurer*, Dr. J. Lee Morrill; *Pathologist*, Dr. Calvin T. Adams.

American Academy of Medicine.—The Constitution was altered at the last annual meeting, so as to admit, in addition to those possessing the degrees of A.B. and A.M., those who can present evidences of preparatory liberal education equivalent to the same. Dr. J. E Emerson, Detroit, Mich., Chairman of Committee on Eligible Fellows, will forward to any applicant copies of the amended Constitution and By-Laws, list of members, and other information as to the Academy. RICHARD J. DUNGLISON, *Secretary*, 814 North Sixteenth Street, Philadelphia, Pa

Nobody Hurt.—Dr. S. S. Cartwright, of Roxbury, Delaware Co., N. Y., sends us an iron staple, such as is used in fastening wires on fences, half an inch wide and an inch and a half long, and made of one-eighth inch wire, which a boy seven years old swallowed accidentally and passed about thirty-six hours later, without injury to himself or family.

Oxide of Lead in a Loaf of Bread.—The oxide of lead found in the bread of the Chicago baker has been traced to the stencilling of the name of the miller on the bag containing the flour from which the bread was made, the color having been put on so heavily that it soaked through the cloth.

Child Suicides.—Since January 1st, 62 children, 46 boys and 16 girls, have committed suicide in Berlin. Of this number 24 had attained the age of fifteen, 14 their fourteenth year, 9 their thirteenth, while 7 were only twelve years of age, and 1 had not attained the age of seven. In most of the cases the immediate cause for the act remains a secret, but it is supposed to have been due to exceptional severity on the part of servants or teachers.

A Public Hospital for Norwich, Conn.—Mr. W. A. Slater has given $100,000, and Mr. Wm. W. Backus $50,000, for the purpose of erecting a public hospital at Norwich.

Dr. James H. Fenner, of this city, died on November 6th, aged seventy-eight years.

A Mohammedan Female Physician.—Dr. Razie Koutlairoff-Hanum, a young Mohammedan woman, who was born in the Crimea, recently passed a creditable examination as physician and surgeon at Odessa, and now enjoys the distinction of being the first woman of her creed to engage in the practice of medicine as understood by Western nations.—*Medical News.*

A Hospital in Central Africa.—As an instance of the civilizing work now being carried on in the Congo Free State may be mentioned the Bangala-station hospital, in the upper Congo basin, a little less than a thousand miles from the Atlantic coast. It was erected for the employés of the station, and contains forty beds, besides rooms for convalescent patients.—*Medical News.*

The Death of Dr. Henry J. Bigelow occurred on October 30th, at his home in Newton, Mass. Dr. Bigelow was born in 1820, and became first prominently known through his essay on Orthopedic Surgery, in 1844, for which he received the Boylston prize. Since this he made many important and original contributions to surgical science, the most notable being his invention of the operation of lithotrity. The French Academy of Medicine awarded him a prize for the operation in 1882, although the medical profession, both in this country and abroad, had long before recognized its value and resorted to it. Harvard University conferred the degree of LL.D. upon Dr. Bigelow in 1882, and he was made Emeritus Professor of Surgery in Harvard Medical School. He retired from the practice of medicine in 1886. For a long period Dr. Bigelow was a sufferer from gastric and hepatic disease, and his death was not unexpected by his friends.

The Death of Professor von Nussbaum, of the University of Munich, occurred on October 31st. The deceased was sixty-one years old. He is reported to have been ill for the past year as the result of an attack of influenza.

A Death during Etherization occurred at the Brooklyn City Hospital on October 29th. About four drachms only of the ether had been administered when respiration suddenly ceased, and a few seconds later the heart's action became imperceptible.

The International Medical Congress at Berlin.—The first volume of the "Transactions of the International Medical Congress" at Berlin is already in the press, and will be published in November. In addition to the business part of the proceedings, lists of delegates, members, etc., it will contain the report of the general meetings of the Congress. The work of editing the "Transactions" is in the hands of a committee composed of Professors Virchow, von Bergmann, and Waldeyer. The expenses incurred by the city of Berlin in connection with the recent International Medical Congress amount to some 80,000 marks, so that, of the sum of 100,000 marks voted by the municipality, a balance of $5,000 remains.

The Action of Chloroform and Ether.—Professor MacWilliam, of Aberdeen, has just published the results of a long and elaborate investigation of the above subject, covering a period of two years, in which a new method of studying the heart and blood-vessels has been adopted. His report is presented to the Scientific Grants Committee of the British Medical Association. It is demonstrated that chloroform exerts a direct influence on the heart—depressing its energy, diminishing its tone, and dilating its chambers. Moreover, such a depressing effect may be brought about by chloroform when given mixed with abundance of air (under four per cent. of chloroform vapor), and when the amount of the anæsthetic administered is not sufficient to abolish the conjunctival reflex. The mode of cardiac failure under chloroform is not a sudden arrest of the rhythmic action, but a more or less sudden dilatation and enfeeblement of the organ, causing the rhythmic contraction to be ineffective. Examples are given of death from cardiac failure while the respiration went on for many minutes. The different action of ether as compared with chloroform is strikingly marked. Ether usually causes abolition of the conjunctival reflex and profound anæsthesia with no depression of the heart, or only a brief and trivial one.

Small-pox Extinct in Ireland.—Not a single death from small-pox was registered in Ireland last year. From this scourge, at all events, "the distressful country" appears to be gradually freeing itself. Over the last ten years the average annual number of deaths was one hundred and thirty, but this average is due to the more serious state of things prevailing in the early stages of the decade. Since 1883 there has only been one year in which the number of deaths from small-pox was as high as fourteen. That was in 1887. In 1885 there were but four deaths from small-pox registered in Ireland; in 1886, two; in 1884 there was only one; in 1888 there were three, and, as above stated, in 1889 there was not one.

Glück's Ivory.—Some weeks ago the Cincinnati daily papers reported at length upon an operation by Dr. Otto Juettner. The patient was a girl of fifteen, suffering from necrosis of the left tibia. The necrosed bone was removed and a piece of ivory inserted after the manner of Glück, of Berlin. The papers now report that the limb has been amputated. It is difficult, for one who has seen Glück's cases in Berlin, to understand what other result could have been expected.

Brooklyn Ambulance Surgeons are again in trouble. The last time it was over the accident which caused the death of Mrs. Robinson; now it is the death of a man from fractured skull, who was sent to the cell of a police station with the diagnosis of alcoholism.

A Berlin Professor Mobbed.—Dr. Sonenburg, Professor of Surgery at the University, was mobbed and came very near being lynched recently, because, after his coachman had run over a woman and broken both her legs while driving down Unter den Linden, the professor ordered the coachman to drive rapidly away to avoid recognition. The mob caught the professor's carriage, dragged him out of its door, beat him unmercifully, and might have resorted to more desperate measures, had not a large body of police interfered and locked up the professor.

The Paris Sisters of Mercy.—It is reported from Paris that the Conservatives have commenced a movement for the reinstatement of the Sisters of Mercy in the Paris hospitals. A committee has been constituted to hold meetings in all quarters of Paris, with the object of obtaining the expression of public opinion on the subject. At the meetings politics are to be entirely eschewed, the humanitarian and financial sides of the question being alone treated.

Chloralamide as a Hypnotic.—Dr. G. Generisch has prescribed chloralamide in thirty-two cases, giving thirty grains at night. This dose was generally sufficient to induce sleep within half-an-hour. A more certain effect and a longer sleep was obtained when forty-five or sixty grains were prescribed. He considers chloralamide preferable to other hypnotics, both because it acts more decidedly and because it is less unpleasant to take. It must be remembered that its effect is negative when sleeplessness is due to pain. It is not by any means a dangerous drug, but headache and vomiting may occur after a very large dose. It does not seem to affect the digestion nor the renal functions. The pulse generally becomes softer and more frequent.

Infant Feeding in India.—Mother's milk, says Dr. Macleod, is always considered by the people of India as insufficient to sustain infant life, and various kinds of milk or other artificial kinds of food are suggested by wise friends to replace it. Cow's milk is generally used as infant food by all middle-class people of Bengal. Donkey's milk is largely consumed in rich families. The Mohammedans, whether rich or poor, prefer goat's milk to any other of its kind; while sheep's milk is considered to be the best article of food by the people of the Northwestern Provinces. Instances have been known where mothers with full breasts and an abundant supply of milk have kept their offspring entirely upon artificial food and thus invoked disease.

An Anencephalic Fœtus Born Alive.—In the *Siglo Medico* Dr. Bernal relates that on August 6th a full-term male child was born at Navalengua which presented the following peculiarities: The whole of the frontal and both parietal bones, and half of the occipital bone were wanting, together with the brain and the optic nerve; the cerebellum was represented by a fungous tissue floating in a large quantity of liquid, black-looking blood, the whole being covered with a very thin pellicle. The face was dark purple in color and the ears were wanting. The eyeballs, nose, and mouth, as well as the rest of the body, were perfectly developed. When Dr. Bernal saw the child, six hours after its birth, it was still alive, but it died two hours afterward, having thus lived eight hours without a trace of cerebral structure. The mother is a healthy, well-nourished woman, aged twenty-three; this was her third pregnancy, the two previous ones having resulted in premature births at the sixth month.

A Novel Feature in Dispensary Service.—One of the latest additions in the way of dispensary service in this city, says the Cincinnati *Medical Journal*, is one of the well-known churches, in which the pastor announces in his bulletin that he has fitted up in connection with his study a completely equipped dispensary for the use of members of his church who desire treatment, and that a well-known eye and ear surgeon, a member of the flock, will render all necessary medical attendance.

The Gastric Juice in Diabetes.—In a long article on the condition of the gastric juice, saliva, and perspiration in diabetes, Dr. Ponomaroff details a number of observations which led him to dispute the assertions of some previous observers—*e. g.*, Heller and Frick, who believed that they had detected sugar in these secretions. With regard to the gastric juice, Dr. Ponomaroff points out that where this is obtained by making the patients vomit, what is obtained is not the gastric juice alone, but an admixture of that with a certain quanty of bile. This generally contains sugar, and therefore vitiates the result. When the œsophageal tube is used and the gastric juice free from bile is obtained, there is, he states, never any sugar in it.—*The Lancet.*

Medical Receptions to Distinguished Guests.—Many of our medical friends from distant places have such good reasons for carrying home with them the pleasant recollections of their visits here, that New York medical men are very properly led to congratulate themselves regarding their reputation for hospitality and good feeling. This is well for both sides—the giver and the receiver. The season is at hand when dinners and receptions are again to be in vogue. Already two such have taken place which have initiated the agreeable service to friends from distant cities. Dr. Landon Carter Gray, of this city, a week ago tendered a reception to Dr. C. Eugene Riggs, of St. Paul, Minn., who came at the instance of the Governor of that State to examine into the asylum systems of New York; and Dr. Seneca D. Powell gave a dinner on Wednesday evening in honor of Dr. William H. Johnston, of Birmingham, Ala. Dr. Johnston was formerly practising here, but years ago left for a new field of labor, leaving behind many personal friends, with whom he served in Bellevue Hospital in good old times, and with whom, at Dr. Powell's residence, he revived the pleasant associations of his younger days.

Obituary.

RICHARD J. LEVIS, M.D.,

PHILADELPHIA, PA.

Dr. Richard J. Levis died November 12th, of pneumonia, at his residence, "Cedar Croft," after an illness of two days. Richard J. Levis was born in Philadelphia, in 1827, and was the son of the late Dr. M. M. Levis. After completing his preliminary education in his native city, he studied medicine at Jefferson College, and graduated in 1848. Dr. Levis was at various periods during his active professional life, surgeon to the Wills Eye Hospital, to the Philadelphia Hospital, the Pennsylvania Hospital, the Jefferson Hospital, and the Philadelphia Polyclinic and College for graduates. From 1877 to 1887 he was President of the Board of Trustees of Jefferson College. He also served as President of the Medical Society of the State of Pennsylvania in 1885, and as President of the Philadelphia County Medical Society in 1885–86. Dr. Levis retired from practice in 1887. An active worker in surgery, he made many valuable contributions to its literature, establishing for himself the enviable reputation of a leading and progressive man.

Reviews and Notices of Books.

THE PHYSICIAN'S COMPANION: A Pocket Reference Book for Physicians and Students. By C. A. BRYCE, M.D. Pp. 164. Richmond, Va.: *The Southern Clinic*. 1890.

THIS little work contains a vast amount of useful material. It is a vest pocket authority on medicine, surgery, obstetrics, infant feeding, and a thousand other matters of practical value to the physician and student. It is clearly and concisely written by an able editor and author, and, to his credit be it said, is more than a mere compilation, much of the work being written from the stand-point of personal experience.

ESSENTIALS OF REFRACTION AND THE DISEASES OF THE EYE, by EDWARD JACKSON, A.M., M.D.; and ESSENTIALS OF DISEASES OF THE NOSE AND THROAT, by E. BALDWIN GLEASON, S.B., M.D. Illustrated. Pp. 276. Philadelphia: W. B. Saunders. 1890.

THIS work is one of a series of "Saunders' Quiz Compends," arranged in the form of questions and answers. Though necessarily superficial, it is of great value to the beginner in these branches, to the student, to the busy practitioner, and as an adjunct to more thorough reading. The authors are capable men, and, as successful teachers, know what the student most needs. Consequently the ground is not only covered, but the points that need most careful elucidation are made clear and easy. All in all, it is a valuable book.

A COMPEND OF EQUINE ANATOMY AND PHYSIOLOGY, by WILLIAM R. BALLOU, M.D. Illustrated. Pp. 205. Philadelphia: P. Blakiston, Son & Co. 1890.

THIS book fills a long-felt want among students of veterinary surgery, and will be warmly welcomed. The author is a thorough student of comparative anatomy, a clear, concise writer, and, as he is professor of Equine Anatomy in the New York College of Veterinary Surgeons, is authority on this subject. Consequently his work is pleasing and can be relied upon. The illustrations are handsome and clear, and add a great deal to the value of the compend.

PROTOPLASM AND LIFE, Two Biological Essays. By CHARLES F. COX, M.A. Pp. 67. New York: N. D. C. Hodges, 47 Lafayette Place. 1890.

MR. COX is an expert microscopist, and for some years was president of the New York Microscopical Society. In his excellent little work, he gives his views on the spontaneous generation theory, with its relation to the general theory of evolution, and also on protoplasm and the cell doctrine. The book likewise contains an excellent *résumé* of the history of the latter doctrine, and every physician will find both pleasure and profit in reading the essays.

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY. First Session. Together with the Proceedings of the Meeting for Organization. Edited by WILLIAM PERRY WATSON, M.D. Volume i., 8vo. Pp. 329. Two Illustrations. J. B. Lippincott Company. 1890.

THIS Society, which was organized at Washington on September 18, 1888, now consists of forty-six members, and the volume now presented is a very creditable one, containing twenty-four papers. The president's address on the "Relations of Pediatrics to General Medicine," by Dr. A. Jacobi, of New York, is as characteristically interesting as are all his writings. Dr. Francis Huber, of New York, reports a very interesting case of "Double Empyema," and Dr. Charles W. Earle, of Chicago, an equally interesting case of "General Subcutaneous Emphysema." On "Infant Feeding" are two valuable papers by Dr. A. V. Meigs and Dr. J. Lewis Smith. Dr. J. O'Dwyer reports on a case of "Diaphragmatic Hernia with Operation." The points of interest in this case were the fact that the physical signs were identical with those of empyema; the frequent high temperatures, for which there was no apparent cause except constipation; the futility of operation in diaphragmatic hernia of long standing, in which a large mass of intestines occupy the pleural cavity, and that the point of election for the operation is through the thorax in preference to laparotomy. Dr. Henry Koplik appears with a very exhaustive paper on "Tuberculosis of the Testes in Childhood." Dr. Henry N. Vinburg discusses the subject, always an interesting one, "Practical Points in the Diagnosis and Treatment of Malaria in Children." There are many other valuable and interesting papers, but there are two that deserve especial mention: "A Study of Some of the Bacteria found in the Fæces of Infants affected with Summer Diarrhœa," by Dr. William D. Booker, of Baltimore, and "A Contribution to the Study of Summer Diarrhœas of Infancy," by Dr. John A. Jeffries, of Boston.

INTERNATIONAL ATLAS OF RARE SKIN DISEASES. Editors: MALCOLM MORRIS, London; P. G. UNNA, Hamburg; H. LELOIR, Lille; L. A. DUHRING, Philadelphia. Publishers: Leopold Voss, Hamburg and Leipzig; H. K. Lewis, London; G. Masson, Paris; J. B. Lippincott Co., Philadelphia.

NUMBERS one and two of the "International Atlas of Rare Skin Diseases," comprising the volume for 1889, have been received. The work presents a really attractive appearance. The colored plates are beautifully executed, and the text, printed in German, French, and English, is inviting. This is an excellent feature of a work whose contributors and readers are of different nationality, for descriptions of lesions, and histological appearances especially, lose somewhat in translation, and the finest points are most easily overlooked by those not thoroughly grounded in the foreign tongue. Though intended more particularly for the specialist, this atlas will undoubtedly give assistance to the general practitioner in the study of his anomalous cases.

The numbers so far issued are somewhat disappointing as regards the subjects treated. We had expected such a work to present almost exclusively unique, hitherto undescribed and unclassified, or at least extremely rare, diseases. The plates illustrate lymphangioma circumscriptum, which is indeed quite rare; ulerythema acneiforme, a term employed by Unna to designate a disease beginning with inflammatory erythema, and leading without suppuration or ulceration to cicatricial atrophy; semisclerotic lupus of the tongue; sarcoma pigmentosum diffusum multiplex, which, though not common, has been already pictured and described; keratodermia symmetrica erythematosa; angeikeratoma, a rare affection of the hands, illustrated by an excellent plate; and lastly, ulcus molle of the breast, this occurring in a patient having chancroids upon the genitals is not so remarkable when we remember the ease with which auto-inoculation can be produced upon any region of the body. The intent of the work, to illustrate the advances in dermatology, is an excellent and desirable one, but subsequent numbers should differ more widely from former publications. The uniform arrangement of the descriptive text is an especially commendable feature.

Two fasciculi will be issued each year.

The Paris Municipal Council has decided to establish an asylum for women certified by the medical staff of the municipal dispensary to be suffering from venereal disease. This establishment is to be altogether distinct from the S. Lazare prison and from the ordinary penitentiaries.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 28, 1890.

T. MITCHELL PRUDDEN, M.D., PRESIDENT PRO TEMPORE, IN THE CHAIR.

Tuberculous Ulcer of the Tongue.—DR. CHARLES N. DOWD presented a patient, aged forty-two, suffering from tubercular disease, which had first manifested itself about two years ago by a fistula in ano. This was cut, but has never healed. About a year ago the patient began to have a cough, with night-sweats, became weak, and emaciated steadily. He had had no hæmoptysis nor long-continued diarrhœa. About four months ago a large ulcer appeared upon the tongue and the man came to Roosevelt Hospital for treatment. The ulcer was on the middle of the dorsum of the tongue, about one and one-half inch from the lip, and was on a hard base somewhat excavated. Those who saw the patient were at first doubtful whether it was a tuberculous ulcer or one growing on a carcinomatous base. A piece was removed and sent to the laboratory of the College of Physicians and Surgeons for examination. The result of the microscopical examination showed it to be a tuberculous ulcer pure and simple; tubercle bacilli were found in fair numbers. A study of the literature of the subject showed that the dorsum of the tongue was comparatively rarely the seat of tuberculous ulcers, especially the medium line of the dorsum, the base and edges being the most common seats of the disease. The case was interesting also for the reason that the general symptoms were not to be accounted for by the signs present in the lungs. He had emaciation, progressive weakness, a cough, night-sweats, and the fistula—all pointing to tuberculosis, but there were no pulmonary symptoms sufficient of themselves to warrant a diagnosis of tubercular disease.

DR. CURRIER said that he had several years ago seen a number of cases very similar to the one here shown. The burrowing was a very characteristic feature of the disease. The diagnosis, when the ulcer is on the edge of the tongue, is very difficult to make, especially if there happen to be a rough tooth which might be the cause of the abrasion. Neumann always laid great stress on the presence of degenerative changes at the apices of the lungs.

DR. J. S. ELY said that he gathered from Dr. Dowd's remarks that he laid some stress on the fistula as being the primary source of the tuberculosis. The speaker, however, could not well understand how the infection of the tongue could have come from the anal lesion without first the production of a general tuberculosis—in other words, the channel of infection must be through the blood circulation in such a case. He thought it was very probable that the man had miliary tuberculosis in his lung, and that infection occurred through the sputa, some bacilli being swallowed and thus leading to the fistula in ano, others lodging on the tongue and setting up the disease in that place. It would seem rational to assume that the ulcers should be on the tip or the edges of the tongue rather than on the dorsum.

DR. DOWD said that he did not at all wish to convey the idea that the tuberculosis of the tongue came by direct infection from the fistula. He agreed with Dr. Ely as to the probable source of the infection.

DR. PRUDDEN thought it worthy of remark that the diagnosis nowadays generally rests upon the microscopical examination, and this should be made with great care, since we would not be likely to find a great number of bacilli. He had seen three cases in the last four years, and in all of them the bacilli were very few. He thought it was the rule that, in these local lesions, the bacilli were not found in such comparatively large numbers as Dr. Dowd had seen in this case.

Recurrent Carcinoma of the Thoracic Wall.—DR. GEORGE C. FREEBORN presented some specimens with the following history: The patient, a woman, aged thirty-two, had had the breast amputated for carcinoma. One year and a half later she was admitted into the New York Cancer Hospital, having a secondary growth in the cicatrix. The following description is taken from the records of the hospital. "At the site of the right breast there is a white cicatrix extending into the axilla and terminating at the median line of the anterior chest-wall in an irregular cicatrix. Above and to the right of the cicatrix there is an irregular swelling over the third and fourth ribs. The mass is immovable and the skin is not attached to it. In the cicatrix are three small nodules, one lying at the junction of the costal cartilages with the sternum." On July 2d, at the urgent request of the patient, the growth was removed. On July 4th symptoms of effusion into the pleural cavity appeared, and these were markedly increased on the 10th, when the dressings were removed, but no signs of pus could be found. The patient gradually grew worse, the chest symptoms increasing, and she died on October 19th.

Autopsy.—An irregular nodular mass, 15 ctm. in length and 11 ctm. in width, occupied the right and anterior surface of the chest-wall, and projected 3 or 4 ctm. above the level of the skin. Upon opening the thorax the right lung was found compressed backward against the spinal column by the new growth, which was found to fill completely the right thoracic cavity. Numerous secondary deposits were found in the lung, the diaphragm, and the liver. Upon making a vertical section through the tumor the cut surface measured 22 ctm. in length and 11 ctm. in an antero-posterior direction. The growth had pressed inward between the ribs, which were, however, not involved. Microscopical examination showed the new growth to be an alveolar carcinoma. The special point of interest in the tumor was its rapid growth. On July 2d the only visible growth was removed, and in three months this large mass had been produced.

Tuberculosis of the Breast.—DR. JOHN S. ELY presented a specimen removed by operation from a woman about thirty-five years of age. She came to Bellevue Hospital complaining of a hard growth in the neighborhood of one breast which extended toward the axilla. Examination showed one very hard nodule in the breast, and from that a chain of enlarged glands stretching toward the axilla. A diagnosis was made of tuberculosis, and the breast with the enlarged glands were removed together. Examination of the specimen showed the nipple drawn out, bearing evidence to the fact that the woman had suckled children. At the edge of the breast was one large gland which seemed to be the apex of a triangular chain broadening out as it approached the axilla. Microscopical examination of these glands showed them to be tuberculous, the proof of this resting upon the structure and the presence of tubercle bacilli. The question which presented itself was how this process had begun. The woman gave no evidence of tuberculosis in any other part of the body, although a very careful examination was made. In the absence of any other explanation he thought it not improbable that the tubercle baciili had been absorbed through the nipple into the galactiferous ducts and had been carried to the first glands, thence radiating out, as one would naturally expect. The wound of the operation had healed, and the woman was perfectly well at the time the presentation was made. Dr. Ely said that he imagined that, in some way or other, tuberculous sputum had gotten on to a rag which was used to cover the breast; the bacilli had then been carried into the openings of the galactiferous ducts. In looking up the literature of the subject he had found several cases in which a similar explanation of the causation of the disease had been offered. Verneuil believed this to be a not uncommon mode of infection in cases of tuberculosis of the breast.

DR. PRUDDEN said that he should be disposed to be rather cautious in making so definite an assumption as to the way in which infection had occurred. As any one

knows, an abrasion of the skin may occur without much notice being taken of it. He would prefer to regard the mode of infection suggested by Dr. Ely as the more probable one, though by no means as the only possible one.

DR. ELY said that in cases of local infection there was generally a local manifestation of the disease.

DR. PRUDDEN replied that this was not always the case. There were several cases on record in which there had appeared a local tuberculosis of the skin without the evidences of any injury locally.

Multiple Gummata of the Lung.—DR. R. G. FREEMAN presented some specimens illustrating this condition. There was no previous history of the case. The woman was about thirty years old. At the autopsy there was found a pelvic cellulitis, chronic oöphoritis, and a purulent salpingitis. The lungs were congested. A single round, whitish nodule, about one centimetre in diameter was seen in the lower part of the upper lobe of the left lung just under the pleura. On closer examination three smaller nodules were found near by. These varied in size from one-fourth to one-half centimetre in diameter. On microscopic examination these nodules showed the structure of gummata. The lung tissue showed considerable interstitial pneumonitis. No gummata were found in other organs.

Syphilitic disease of the lung is rare. Many cases are reported as syphilitic pneumonia where the grounds for the diagnosis of syphilis are insufficient, and which are either chronic interstitial pneumonia or tuberculosis. T. Lang, quoting Petersen, gives statistics of one hundred and eighty-three cases of syphilis involving the different organs as follows: Liver, 79; kidneys, 34; spleen, 33; lungs, 11; heart, 10; brain, 9; intestine, 7. Dr. Northrup reported a case to this society about a year ago, in which there were miliary gummata of the lungs, liver, kidneys, and lymphatics in a child nine months old.

Alternate Paralysis due to Multiple Areas of Softening in the Pons Varolii—DR. IRA VAN GIESON reported the following case: Bridget B——, forty years of age, admitted to Charity Hospital July 16, 1889. Her sickness had begun one week before by falling suddenly to the ground. She got up again and was able to walk alone, but was weak in the left leg. On reaching home she became unconscious, and when she recovered from this she was aphasic and had left hemiplegia and right facial paralysis. The mouth was drawn to the left, and there was dribbling of saliva, and deglutition was difficult, especially for fluid. She remained in this condition for the next four months. Examination of the heart and lungs gave negative results. The aphasia became gradually somewhat better. About a week before death a persistent low temperature was noticed, the tongue became coated, and the woman gradually failed and died on December 16, 1889.

Autopsy.—The lungs were œdematous, heart normal, liver fatty in spots, the kidneys showed the changes of a severe atrophic chronic nephritis. There was nothing noteworthy about the other thoracic and abdominal viscera. The pia mater showed a few nebulous striæ over the convexity and there was considerable sub-pial fluid. A section of the pons at its junction with the medulla showed a spot of softening confined to the right pyramid, and two small spots of softening, two to four millimetres in diameter, one situated between the left pyramid and the raphé, and the other in the floor of the fourth ventricle on the right side between the raphé and the nucleus of the sixth nerve.

Microscopical Examination.—Under the microscope these spots of softening were seen to involve the following structures: 1. Nearly the whole of the right pyramid as it passes from the pons to the medulla. 2. A portion of the posterior longitudinal fasciculus of the right side and the right facial nerve bundle just as it turns downward to pass to its nucleus. The right sixth nerve nucleus was not damaged by the softening. The facial nerve bundle was cut off from its nucleus by this minute area of softening, and in sections stained by Weigert's method the degeneration of its fibres (peripheral of the spot of softening) was shown very well. The degeneration of the facial nerve bundle was shown best in sections of the medulla above the spot of softening, in that portion of the genu facialis nearest the raphé, where the fibres are cut transversely as they pass downward and backward to the nucleus of the facial nerve. In such sections the genu facialis was very thoroughly degenerated.

The symptoms in this case corresponded very well with the lesions in the pons. The softening of the right pyramid produced the left hemiplegia, and the destruction of the facial nerve bundle in the pons on the right side caused the right facial paralysis, making the case one of alternate paralysis.

Healed Tuberculosis.—DR. T. M. PRUDDEN presented a specimen illustrating a localized so-called healed tuberculosis of the bronchial glands. The lungs were removed from the body of a woman who had died from pernicious anæmia. There were two little tubercles, one about three millimetres in diameter, and the other half this size. There was also pigment in the lymph nodes at the base of the lungs. Dr. Prudden said that he had presented the specimen because it was a good illustration of this not uncommon condition, and also because it showed how easy it would be to overlook tuberculosis of the lungs. If this lung had not been cut exactly right the lesion would have been overlooked, and it would not have been suspected that it was the source of infection.

Supposed Tuberculous Infection from the Pharynx.—DR. WILLIAM P. NORTHRUP presented some gross specimens and slides illustrating a case of retro-pharyngeal abscess, tubercular meningitis, and calcareous bronchial lymph nodes. They were removed from the body of a boy, three and one-quarter years old. He was returned to the New York Foundling Asylum two weeks before death with no history, except that the nurse said she was afraid it would smother in the night. When brought to the hospital dyspnœa was very marked. Fluids could be swallowed well, but there was a post-pharyngeal swelling crowding the tonsils back out of sight. The swelling nearly filled the pharynx, was tense, slightly red, not tender, and apparently not acutely inflamed. The position of the head was constrained, and there was a moderate swelling on the left side of the neck. The abscess was opened through the posterior wall of the pharynx, and there was a free discharge of pus and disappearance of the tumor. One week before death the temperature gradually rose from 101° to 103° F. The head was rigid, but there was no pain on motion. The child became apathetic; there was moderate dyspnœa, vomiting, constipation, and screaming at night. The operation wound was patulous, the mucous membrane of the pharynx showed enlarged follicles, but there were no tubercles. There was no caries of the spine, the abscess was submucous, and there were no sinuses leading from it. The retro-pharyngeal glands were enlarged, not tubercular. In the lungs were signs of bronchitis, congestion, and œdema. The bronchial glands were large, red, and soft. There were no recent tubercles. On further careful examination in alcohol, while cutting in a series transversely, a long, narrow, chalky mass, flattened up against the trachea, was encountered. This was obviously the remains of a fused mass of broken-down cheesy glands, and might easily have been overlooked. The liver, spleen, kidneys, stomach, and intestines were normal.

Microscopical Examination.—Tubercles and tubercle bacilli were found in the meninges, but none in the abscess-wall or tissues about it.

The interest in this case resides in the fact of the presence of tubercular meningitis with retro-pharyngeal abscess, and the single chalky mass. The speaker said that he had recently presented before this society a case of general tuberculosis having its oldest process in the mesenteric lymph nodes, with no tubercles at all in the bronchial lymphatics. It is the usual experience, in

autopsies on children, to find the oldest tuberculous process in the nodes grouped around the largest bronchi near the tracheal bifurcation and at the root of the lung. When this autopsy was made the question arose as to whether the retro-pharyngeal abscess was not the beginning and the meningitis the ending of the same disease. The bronchial glands appeared normal in the fresh state, and this seemed to rule them out, but the subsequent examination revealed disease. The case seems to emphasize two points, viz., 1, the value of searching for the oldest tuberculous process, and that most carefully. When this specimen was placed in alcohol for further examination it was believed to have been ordinarily well looked over and searched for cheesy centres. It was a matter of surprise, then, when the razor grated against the long, chalky mass; 2, the case also emphasizes the fact, so often observed, that if a very large percentage of cases are carefully examined, the oldest process will be found in the lymph nodes clustered about the respiratory ways.

The Society then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 28, 1890.

A. S. HUNTER, M.D., PRESIDENT, IN THE CHAIR.

The Treasury.—The Treasurer's report showed a balance of $1,714.

Report of the Censors.—This report included that of the counsel for the Society. The number of trials for the illegal practice of medicine—charlatanry—had been constantly diminishing, due doubtless to the steps taken by the Society the past few years in seeing that the law regulating the practice of medicine was duly executed. Yet there were thirteen convictions obtained the past year, and numerous cases investigated. The counsel thought that the recent legislative enactment providing for a board of medical examiners would have a good effect.

Annual Dues.—On motion of Dr. Daniel Lewis the annual dues were continued at three dollars.

Committee on Hygiene.—DR. SIMON BARUCH read the first part of the report, which discussed among other points the question of establishing public baths. After pointing out the health advantages of cleanliness, the best and most practical form of public baths was considered. They must be located in the centre of crowded districts, be modest in order not to be too expensive, so constructed that a cleansing bath could be obtained without much trouble, expense, distant travel, or outlay of time. The shower-bath met these indications better than the plunge- or tub-bath. Less room, less water, less outlay for plant was required than for the tub-bath; it required less time, involved no danger of communicating disease, and so little trouble and expense, and returned such an amount of comfort that even the veriest tramp would cease to go dirty.

The Hygiene of Public Schools.—The second part of the report, dealing with the hygiene of the primary schools, was read by DR. H. D. CHAPIN, who had made several tours of inspection in some of the school districts. He found most of the primary schools greatly overcrowded, individual classes much too large, many benches to which there was no desk, insufficient light (requiring gas); positively bad ventilation; odor of water-closets in the school-rooms; no place to hang clothes; in short, the condition in many instances was about as bad as it well could be.

Prize Essays.—The committee (Dr. Bangs, Chairman) reported that three essays had been received in competition, and it was decided to award the prize of one hundred dollars to the author of the essay entitled "A Physiological and Therapeutic Study of Hydrastis Canadensis." It proved, however, that the author of this paper was a Philadelphian, not a member of the Society, while the object in offering the prize was to stimulate scientific research among the members. The comitia minora was given power to act.

Change of the By-Laws.—The proposed changes in the by-laws, reducing the initiation fee from five to two dollars, and making the editor of the Directory a member of the comitia minora, was carried.

Officers Elected.—*President*, Dr. Orlando B. Douglas; *Vice-President*, Dr. Arthur M. Jacobus; *Secretary*, Dr. Charles H. Avery; *Assistant Secretary*, Dr. William E. Bullard; *Treasurer*, Dr. John S. Warren; *Censors*, Drs. George E. Abbott, Alexander S. Hunter, William McLaury, Richard Van Santvoord, and S. O. Vander Poel.

TRI STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held at Turner Hall, Chattanooga, Tenn., October 14, 15, and 16, 1890.

J. B. COWAN, M.D., PRESIDENT, IN THE CHAIR.

Report of a Case of Cancrum Oris, or Gangrenous Stomatitis, by DR. W. P. MCDONALD, of Hill City, Tenn. The patient, white, was four years of age; first seen on August 5th. Found with some fever, tongue coated brown, with red edges, surface more or less furrowed or full of cracks in the brown coat, general appearance indicating a very low state of health. Bowels were inclined to be too loose, and abdomen seemed to be somewhat distended and tympanitic.

Fourteen days after seeing the child for the first time the mother was found with nearly the same symptoms as the child first presented. The child was still improving, but complaining of a sore mouth. On examination he found several small ulcers on the right side of the mouth, with a general inflammatory appearance of the gums and whole mucous lining of that side of the buccal cavity, with some bleeding from around the teeth. The trouble at first seemed to yield to a wash of chlorate of potassium and creosote, but on the seventeenth day of illness the inflammation increased rapidly, the whole cheek and side of the face appearing very much swollen, and the inside was fast becoming dark and gangrenous. August 24th a small dark spot, about the size of a penny, made its appearance externally, just at the right wing of the nose. This rapidly enlarged, involving the wing of the nose and in proportion the tissues on either side of the central spot, and on August 25th it had involved the right side of the nose up to the inner canthus of the eye, also the upper lip to the median line, and had spread rapidly on the cheek, reaching a point where the zygomatic muscles cross the superficial portion of the masseter. The teeth on this side became loose and dropped out, both above and below, indicating deep-seated trouble, possibly involving the maxillary bones.

According to authorities, cancrum oris more frequently occurs as the sequel of other diseases than *per se*. The statistics of Rilliet and Barthez show that out of 98 cases of this disease 41 of them were following measles, 5 scarlet fever, 6 whooping-cough, 9 intermittent fever, 9 typhoid fever, and 7 mercurial salivation.

To draw a conclusion in the case by these statistics, and by watching the case closely from the first, Dr. McDonald asks: "Did this occur as the sequel of the typho-malarial fever which I diagnosed at the commencement of the sickness (remembering the poor state of health the child was in to begin with)? Or, was it the result of mercurial salivation produced by the mercury given at the beginning, and followed two days after by the syrup of the iodide of iron?"

DR. E. T. CAMP, of Gadsden, Ala., once saw a case similar to the one reported, which he pronounced gangrena oris, the whole of one cheek being destroyed. There was evidence of mercury having been taken in the early part of the illness of the patient. The case terminated fatally within a few days. The patient was four

or five years of age, and of the lower class. He thought the gangrene was a result of mercurial poisoning which was administered during the early part of the illness.

On all Sides a Learned Doctor. — Dr. James E. Reeves, of Chattanooga, made an earnest plea for higher medical education, stigmatizing cheap medical colleges with no facilities for imparting instruction as the greatest stumbling-blocks in the way of true progress.

Fracture at Elbow-joint.—Dr. Andrew Boyd, of Scottsboro, Ala., reported several cases. He said after reduction there are but two methods of treatment of fracture at the elbow-joint, viz., the extended or straight, and the flexed position. The author thinks the flexed position the better, for the reasons: 1. That in all cases we fear anchylosis, and it is much better to have a flexed anchylosed arm than a straight one. The comparative use in each is apparent. 2. When the splints have remained twenty five to thirty days, the arm is atrophied and almost helpless; it is therefore easier to overcome the flexor muscles than the extensors, and a patient can extend an arm with more ease than he can flex it.

Expert Testimony.—Mr. Sydney B. Wright, of Chattanooga, read a paper and drew the following conclusions:

1. That the circumstances from which the conclusion is drawn should be fully established. 2. That all the facts proved should be consistent with the hypothesis. 3. That the circumstances should be of a conclusive nature and tendency. 4. That the circumstances should, to a moral certainty, actually exclude every hypothesis but the one propounded to be proved. 5. That mere circumstantial evidence, unless the chain of circumstances is absolutely complete, ought in no case to be relied on where direct and positive evidence which might have been given is withheld by the adverse party.

Case of Neurosis.—Dr. W. G. Bogart, of Chattanooga, reported a case in detail.

A few Remarks on the Fevers of Middle Tennessee and their Treatment.—Dr. J. C. Shepard, of Winchester, Tenn., said the great malarial period extended from the settlement of the country up to about 1840, during which all the fevers of the country were malarial and periodical. Commencing about 1840, the great typhoid period extended until near 1860. During this period malarial fevers were almost, if not entirely, unknown, and typhoid was dominant everywhere and every case was typical. About 1860, or a little sooner, there was a return of malarial fever, but in connection with typhoid fever. This was the typho-malarial period, which continued for fifteen or twenty years. About 1880, or somewhat earlier, the characteristic symptoms of both typhoid and malarial fevers commenced to disappear, and have continued until now. This is the period of *fusion*. We now have only one fever, which is a continued fever, not typically typhoid, nor malarial, nor even typically typho-malarial. There is not now, nor never was, a continued malarial fever, *per se*, in Middle Tennessee.

A Contribution to the Study of the Continued Fevers of the South.—Dr. L. P. Barber, of Tracy City, Tenn., said the continued fever of the South, its nosology and etiology, forms a subject now justly attracting much attention, a subject on which much is yet to be learned, and over which the medical world is considerably at variance. Only a close and accurate study of the disease by competent observers, in many and different localities, and a thoughtful comparison of these observations, with free discussion, will advance our knowledge of its nature, and shed light on the vexed question of its cause.

Silicate of Soda, Some New Methods of Use in Surgery, by Dr. George A. Baxter, of Chattanooga. The paper chiefly had reference to a silicate jacket made by a new process of hardening the silicate, which, it is claimed, is an improvement on all other jackets, inclusive of the plaster-of Paris, leather, woven wire, or watch-spring, now in use for the treatment of spinal injuries or disease. It is lighter, equally durable, equally immobile when on, and capable of removal at any time, and of adjustment to any lateral pressure desired.

Abscess of the Liver.—Dr. Richard Douglass, of Nashville, said that abscess of this organ is the result of absorption of some morbid product from the intestine, or from some ulcerated surface. The bacteria enter the circulation and are deposited in the liver, where abscess is formed. This may be with a normal temperature. He said that phagocytosis may furnish an explanation of the occurrence of abscesses in the various tissues and organs of the body, including the liver.

Uterine Fibroma.—Dr. J. B. Murfree, of Murfreesboro, Tenn., said a uterine fibroma is a morbid growth developed within the walls of the uterus, and is composed of muscular fibre cells, fibro-plastic material, and cellular tissue, and is due to a perversion of nutrition. It is non-malignant and homologous in its structure. Pain, hemorrhage, rectal and cystic irritations, indigestion, dropsy, and exhaustion are some of its results. They threaten life by hemorrhage, inflammation, septicæmia, and pressure. The treatment is divided into four methods: 1, Symptomatic; 2, general (by medicines); 3, electrolysis, and 4, surgical.

Laparotomy *versus* Electricity in Ectopic Pregnancy.—Dr. Wathen, of Louisville, Ky., said that electricity, the only fœticidal means now recognized as orthodox by physicians who practise destroying the life of the fœtus in ectopic pregnancy without laparotomy, is no longer used for this purpose where the pregnancy has continued beyond three and a half or four months, and is seldom used after the third month. At this time the fœtus cannot be killed except by electro puncture, and the complications and the deaths consequent upon this practice have been so numerous that the most radical advocates of electricity are afraid to introduce the electrodes into the gestation sac. The use of electricity in extra-uterine pregnancy is practically confined to the United States, and while it is advocated by men of recognized ability and learning in obstetrics and gynecology, he was constrained to believe that very soon it will have no support. Dr. Wathen then entered into an argument in favor of laparotomy, for the difficulty and sometimes the impossibility of diagnosticating extra-uterine pregnancy in the early months is so manifest to experienced physicians that it would be ridiculous to claim that in all these cases pregnancy existed; while in the cases where laparotomy is done a diagnosis may positively be made by seeing the embryo or the chorionic or placental villi.

Hypertrophy of the Tonsils.—Dr. T. Hilliard Wood, of Nashville, Tenn., said with reference to operative treatment, excision by the tonsillotome is most popular, although the writer prefers the bistoury and vulsellum forceps. The operation is rendered painless by applying to the tonsil a solution of cocaine, and by injecting, with a hypodermic syringe, a few drops of the same solution into the substance of the gland. As a rule, general anæsthetics should not be used.

Case of Remarkable Injury, with Recovery, by Dr. E. A. Cobleigh, of Chattanooga.—A heavy drill, while being lowered into a well by a rope, slipped from its fastening, and falling a distance of forty-five or fifty feet struck the man on the back of the neck and ploughed through the tissues, to emerge from the right side of the chest, there protruding about eight inches, absolutely impaling him. He stepped down from the platform, supporting himself against the side of the well, and called on a fellow-workman to pull out the drill. A stalwart negro with both hands tried to pull out the drill, but failed. He mounted the platform and tried again by a steady pull, which did not budge the impaling instrument; and in his excitement to get the thing out, he gave it that to-and-fro motion, with the powerful leverage of the long handle, which one sees resorted to in pulling posts out of the ground. At this procedure the drill loosened and he extracted it from above, just the reverse to its direction of entry.

The patient was now placed in a bucket, very imper-

fectly fastened to the well-rope with a noose passed aronnd him, and holding himself mostly by his own efforts, was drawn to the surface, placed in a chair, and conveyed to the work-room adjoining the office. The patient is twenty-eight years of age, stands five feet and eleven inches high, and weighs one hundred and eighty-five pounds, having a magnificent physique.

Examination developed the fact that the wound of entrance was situated one inch and a half to the right of the spinous process of the fifth cervical vertebra, just at the point where his neck began to broaden toward the shoulders, and the drill had only missed the spinal column by a hair's-breadth. Passing downward and very slightly foward and to the right, leaving a rather smooth opening oval in form from above (perpendicularly), with somewhat inverted edges, it resembled the old-fashioned wounds of entrance of round shot, not very large—not so immense as one would expect from the size of the wounding instrument, yet sufficiently so for the cervical muscles and fascia to show plainly in the wound, especially if forcibly opened. The shape of the wound made it close like a valve, yet air was entering and being expelled with a pink froth at nearly every respiratory effort, though there was no considerable hemorrhage.

From here the drill passed into the chest cavity between the scapula and the clavicle, at its very apex, without damage to either of these bones, impinging on the third and fourth ribs, which were both fractured from behind right in the line of the wound—evidently the fragments being parted as by a wedge while the drill was *in situ*—then passing down on the anterior and outer surface of the fifth and sixth ribs without injury to either, and emerging by a great gaping and ragged wonnd, with much eversion of its edges, just at the inferior border of the latter rib and over the interspace below, its centre being at the time of the examination two inches below and one and a half inch to the right of the nipple. There was only moderate bleeding from this wound, into the opening of which Dr. Cobleigh readily introduced the tips of three fingers, and no air was escaping here. The skin and subcutaneous tissues seemed to be so absolntely deadened by the magnitude of the injnry sustained as to have entirely lost all their normal elasticity. He passed two fingers up the tract of the wound their full length, entering the pleural cavity with their tips under the broken ends of the lower fractured rib, which could be distinctly felt. Everything felt torn and indefinite, the ends of the broken bone easily removable, but he was not able by touch to satisfy himself with any degree of reasonable force whether the subjacent lung surface was injured or not, though he thought it was. From top to bottom of the wound, in its entire length, it measured in a direct line at that time fourteen and a half inches, and the patient must have had buried in his anatomy fourteen and a half inches of steel an inch in diameter.

On withdrawal of the fingers the wound closed by collapse of its sides and prevented any profuse degree of hemorrhage externally. There was very intense pain and a marked degree of shock, as shown mainly by the pulse, the mind remaining clear throughout. The integument, however, was quite clammy and the patient complained a great deal of chilliness, without any pronounced rigor. There was extreme rapidity and difficulty of respiration, some gasping, and Dr. Cobleigh was strongly of the opinion that he would die in a short time, especially as he found the signs of depression increasing fast—the pulse losing all tone, flickering, irregular, intermittent, and the mucous surfaces blanching.

Dr. Cobleigh regards the case as one of remarkable recovery, fit to be recorded along with the celebrated "crow-bar" case of Maine, and the later case of abdominal perforation by a railroad coupling-link which happened a few years ago in Kentucky.

Urethral Stricture and its Complications.—Dr. Gibson, of Birmingham, Ala., said that if he were compelled to use only one instrument in the cure of all strictures, he would use the sound. He believed that when it was properly used there were very few strictures that could not be relieved, and better so by it than any other means; and that the only stricture for which it was necessary to invoke the aid of the urethrotome was the old, tight, and unyielding stricture in the pendent urethra and meatus.

Notes on Apostoli's Method of the Treatment of Uterine Fibroids.—Dr. P. S. Hayes, of Chicago, said that one of the best demonstrated facts in the Apostoli operation was the arrest of all uterine hemorrhages excepting those cases that are due to the puerperal condition. All observers unite in recognizing that the positive pole is the one to be connected with the intra-uterine electrode. To the thinking physician the query is, why the positive? And the answer comes that in electrolysis, especially when the electrolyte—the fluid undergoing electrolysis—is blood, the clot formed around the positive pole is small and dense, while that around the negative pole is large and flabby. Knowing, as we do, that oxygen, chlorine, and the acids are liberated at the positive pole when electrolysis is performed on the tissues of the body, and also knowing that hydrogen and the alkalies are liberated around the negative pole, we have only to apply our knowledge of the action of the acids and alkalies, respectively, on the blood to explain the observed phenomena.

Officers for 1891.—*President*, Dr. Robert Battey, of Rome, Ga.; *First Vice President*, Dr. E. T. Camp, of Gadsden, Ala.; *Second Vice-President*, Dr. Richard Douglas, of Nashville, Tenn.; *Third Vice-President*, Dr. D. H. Howell, of Atlanta, Ga.; *Secretary*, Dr. Frank Trester Smith, of Chattanooga, Tenn.; *Treasurer*, Dr. B. S. Wert, of Chattanooga, Tenn.

On motion the Association adjourned, to meet in Chattanooga, Tenn., date to be decided on.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE HARVEIAN ORATION AT THE COLLEGE OF PHYSICIANS—THE RELATIONSHIP OF PHYSIOLOGY TO MEDICINE—ABDOMINAL SURGERY—THE REVIVAL OF THE OXFORD MEDICAL SCHOOL.

London, October 25, 1890.

The Harveian oration for this year at the College of Physicians was delivered last week by Dr. James Andrew, physician to St. Bartholomew's Hospital. After reading a brief extract from the register of Merton College, Oxford, which had been hitherto unnoticed, but which had been brought before Dr. Andrew by the present warden of Merton College, and which fixed the date of Harvey's admission to the wardenship, Dr. Andrew observed that, apart from Harvey's great discovery, his writings contained many things worthy of consideration. We might find in them no doubtful indications of the wise and prudent advice he would have given us for the abatement of some, at least, of the evils under which our profession labored at the present day. Dr. Andrew said he did not hesitate himself to place in the first rank of these ills the enormous amount of so-called medical literature. There was one publication which he regarded with especial horror—the "invaluable" *Index Medicus*. He found that the volume for 1889 contained the names of not fewer than 13,870 contributors, representing not less than 20,000 contributions to medical science during the year.

Alluding to a common reproach cast upon our profession that we pretend to be, and are not, scientific, he proceeded to discuss the relation of medicine to physiology. One of the best definitions of medicine, he said, was that which described it as "applied physiology." If we failed to attain to that ideal, if we were compelled

daily to act upon probabilities in place of scientific certainties, then the blame must rest at least as much on the physiologist as on ourselves; he failed to supply us with the knowledge which we required and which he alone could give us. In saying this, however, Dr. Andrew said he had no wish to ignore the splendid services which physiology had rendered to medicine. He pointed out also that the relationship between them had greatly changed during the last two hundred and fifty years. Such change was a necessary consequence of the progress made by physiology. In Harvey's time, in any classification of the sciences, physiology might have been regarded as a department of medicine; now the reverse would be the case. Physiology by slow degrees had come to rely more and more on purely scientific modes and instruments of research, and to apply them to matters which could be brought to the test of direct experiment. Medicine, on the other hand, had no choice but to remain, so far as it had a scientific side, a science of observation, for anything like effective investigation of the matters with which it dealt, by direct experiment, was impossible. The task of employing physiological results to explain clinical facts or to form the basis of rational treatment became harder than ever. In illustration of these remarks Dr. Andrew referred to some recent experiences of his own in the treatment of hæmoptysis. Quoting from a standard text-book a long list of remedies supposed to be useful for hæmoptysis, he said it was disappointing to find that the drugs which had been proved by direct physiological experiment to be at any rate likely (on the theories of those who proposed them) to be of service in the treatment of hæmoptysis, did not come more distinctly to the front. Physiology, however, was at last overcoming the great difficulties in the way of accurate determination of variations in the pulmonary circulation, and of their causes. The orator then detailed the results of some recent investigations on the subject by Dr. Bradford, Dr. Dean, and Mr. George Henry Lewes.

The Medical Society commenced work on Monday evening last, when the President (Mr. Knowsley Thornton) gave an address on "Abdominal Surgery, Past and Present." Ovariotomy, he said, had been the starting-point of abdominal surgery, and the methods of procedure had been progressively improved until the operation had been shorn of the mortality which in former years made surgeons look upon it as an operation only to be resorted to *in extremis*. The first great improvement was the abandonment of the clamp, and the general use of the ligature was promptly followed by the adoption of the Listerian method, with such success that a powerful impetus was given to the surgical treatment of diseases of the other abdominal viscera. Every surgeon of any eminence had improved his results enormously by adopting the Listerian method, and then, having learned how to be surgically clean, he by and by found out for himself other means of attaining the same end by methods differing more or less from those of Lister. The drainage-tube and flushing the peritoneum with pure water both removed the pabulum which was necessary for the development of pathogenic micro-organisms. As recently remarked by Erichsen, Lister aimed at keeping these micro-organisms out of the wound—an accomplishment which Lawson Tait seemed to think hardly possible. For his own part, he did not doubt the feasibility of the plan, for his own results, with a limited use of the drainage-tube and practically none of flushing, had been at least equal to those of the surgeons who practised newer methods. He had himself always continued to use the original Listerian methods, and he claimed that his results were in a sense more valuable than those of other operators because he had all along steadily adhered to one method. When a surgeon was constantly changing his methods, it was impossible to say whether an improvement in his results was due to his greater experience or to the change of method.

A noteworthy incident in medical education is the revival of medical education at the University of Oxford. There have always, it is true, been a certain number of students who proceeded to Oxford to graduate in medicine. Hitherto, however, they have been students who, having taken a B.A. degree at Oxford (as required by the regulations), subsequently came to London to pursue their medical studies—returning to Oxford only at intervals to pass the stated medical examinations. In most cases, indeed, an Oxford student received his entire medical education in London. Naturally this did not tend to increase the popularity of the Oxford degree. The regulation requiring students to first graduate in arts was not so severe a restriction as might be supposed, inasmuch as, for several years past, science has (as at Cambridge) formed a division of the B.A. degree, and students can obtain the degree by passing almost all their examinations in scientific subjects, among these being physiology. The same latitude in a choice of subjects for the B.A. degree prevails at Cambridge, where, as at Oxford, there is no separate degree in science. (At Cambridge, though, it is not essential to graduate first in arts.) As a medical school, Oxford has long lagged in the rear, and the number of aspirants for its medical degrees have been proportionately small. It is not that its medical examinations are unduly stringent, for they are reputed to be much less severe than those at Cambridge. It is, therefore, gratifying to find that efforts are now being made to put Oxford on a level with Cambridge as a centre of medical education. Additional teaching has been provided, the examinations have been modified, and the time is apparently not far distant when an Oxford student will be able, if he wishes, to obtain his entire medical education at his *alma mater*.

WHICH WAS THE FIRST POST-GRADUATE SCHOOL IN NEW YORK?

To the Editor of the Medical Record.

Sir: In answer to your correspondent "Secretary," in the last number of the Record, I desire to say that the claims of the New York Post-Graduate Medical School to be the first one instituted in New York rest upon the following facts: Seven members of the Faculty of the University of the City of New York resigned their positions at that institution on April 4, 1882, "for the purpose," as they stated, "of founding a Post-Graduate Medical School." They immediately began the work of organization, and on August 19th of that year issued their "Announcement" in the Medical Record, and previously addressed a circular to the profession throughout the country. They commenced their sessions in the College of Pharmacy on November 6, 1882, but they had previously formally opened the college at Chickering Hall, on November 4, 1882.

There was an attempt made to organize a *Poliklinik* in New York in 1881. The writer of this note, among many others, was invited to join in that undertaking, but the attempt was a conspicuous failure for various reasons. The plan was not at all as complete as that subsequently made and carried out by the Post-Graduate Medical School. The undertaking was also handicapped by the name, afterward spelled *poly*, an orthography which made its title neither good Latin, German, nor English. At any rate, not until the Post-Graduate School was well organized, and after its organization had been discussed far and wide, in both lay and professional journals, was the abandoned plan of the *Poli-* or *Poly-* clinic taken up by new men, using the very schemes handed them by those who had failed in a former attempt, one of whom was with us in the Post-Graduate organization. If intentions and abandoned enterprises count, then is the Post-Graduate School still older, because the founders of this institution were made a Post-Graduate Faculty in the University of the City of New York in 1875, and

gave courses of instruction to graduates there. They gave up their name, however, some two years before they resigned to found the Post-Graduate Medical School.

The founders of this latter-named institution, under a hostile fire of malevolent criticism, had burned their bridges and were in full advance, without aid or sympathy from the profession in New York, into the undiscovered country of instruction in medicine for graduates, fully five months before the actual founders of the Polyclinic, with a formidable backing of lay and professional supporters, mustered up the courage to announce that they were coming well in the rear.

The Post-Graduate Medical School hence claims to have originated a plan, and to have been the first to actually announce the formation of an organized system of clinical and laboratory instruction for practitioners in New York. Besides this, we have maintained our rightful position as leaders, by establishing a *bona-fide* hospital as an integral part of our institution. Some years later the same idea was taken up by the Polyclinic.

Yours respectfully,

D. B. St. John Roosa, M.D.

November 4, 1890.

MIXED NARCOSIS AND OPIUM IDIOSYNCRASY—MORPHIA AND ATROPIA BEFORE GIVING ANÆSTHETICS.

To the Editor of the Medical Record.

Sir: In some medical societies there are members who are continually "bobbing up" with a "case" which the paper, remarks, or something else, "has reminded them of."

Kindly indulge the writer along the same line in the brief detailing of an experience which, at the time of the occurrence, was thought to bear directly upon the question asked in your leading editorial of November 1st.

Miss ——, aged about twenty, dark complexioned, black hair and eyes, good physique, well nourished, was given an anæsthetic for the removal of hæmorrhoids.

At the hour of operation she was quiet, not nervous, cheerful—in fact, a case wherein the one who gives the anæsthetic congratulates himself upon having a case that is not likely to give him trouble. Twenty minutes before giving the anæsthetic, one-eighth grain morphia and one two-hundredth grain atropia were given hypodermically. A folded napkin was used as an inhaler and A. C. E. given. When complete anæsthesia was nearly reached, the respiration became feeble and then stopped. Lowering the head soon restored the respiration. Another attempt produced the same results, which yielded to the same respiratory tactics. Efforts were made again and again with the A. C. E., but, as the danger symptoms were more serious, chloroform was tried, and a very few drops not only arrested the respiration, but the lips became cyanosed and radial pulse very weak. Artificial respiration and hypodermics of brandy restored the circulation, and breathing became normal again. It was now noticed that the patient was insensible to everything excepting the itching of nose and face, and so, although she was sufficiently conscious to rub the nose and face, the sphincter was stretched, tumors removed, and stumps cauterized, without pain or struggling. Occasionally a few breaths of A. C. E. were given, but at no time was she completely anæsthetized.

It may be urged that the operation was done in what is called the danger stage of anæsthesia, but faithful efforts were made for forty-five minutes to get beyond, safely, into complete anæsthesia, without success.

The patient's recovery was rapid and satisfactory, but the case evidently contained a lesson for physicians, and the lesson that seems to be taught is, be careful that no idiosyncrasy exists in your patient against the use of morphia before you give it for anæsthesia; and in absence of evidence either for or against, do not give it.

J. L. Tracy, M.D.

1728 Adams Street, Toledo, O.

MORPHIA AND ATROPIA BEFORE ANÆSTHETICS.

To the Editor of the Medical Record.

Sir: I have read with deep interest the article in your issue of November 1st on the hypodermatic injection of atropia and morphia previous to the administration of anæsthetics. As there is considerable testimony adduced in that article adverse to this procedure, I cannot restrain the impulse to give my testimony in its favor. I offer it because I am certain that my experience with the method extends over more time than that of any other man in this country. I believe I can also truthfully say that it is greater, because continued so long and resorted to always for operations of any gravity or duration; while, so far as I can learn, the method is only occasionally resorted to. I learned the advantages of the method from Bernard's "Leçons sur les Anesthésiques," published in 1875, and immediately adopted it. In 1876 I presented its claims to the profession,[1] and again in 1879.[2]

In giving my testimony I appreciate fully how trifling is any individual experience with anæsthetics, unless under very exceptional circumstances. Mine is not even that afforded by a metropolitan hospital, yet it has been uniformly not only favorable to the method, but such as to give me the firmest conviction that decided advantages result from the combination of narcotics and anæsthetics. Emotional disturbance is allayed, a far smaller amount of the anæsthetic is required, the patient remains quieter under the influence, vomiting afterward is markedly less, and the pain of the operative procedures soothed or abolished. As to danger, I have never seen any. Three times I have had most serious symptoms under anæsthetics, in neither of them was this plan followed. In one patient, the worst case of the three, the one most difficult to rescue, I gave the same anæsthetic again about three weeks afterward, and without a single bad symptom, having preceded the administration with a hypodermatic injection of morphia and atropia.

I may say that I always use as an anæsthetic the A. C. E. mixture.

I refer your readers to the articles above alluded to for arguments and further testimony. I could not permit the opportunity to pass without a few words in favor of what I believe to be the most valuable modification of artificial anæsthesia, and would ask from all a careful consideration of the nature and character of the evidence given in your editorial before they reject this method.

J. C. Reeve, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 2 to November 8, 1890.

Crosby, William D., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, granted leave of absence for four days. S. O. 259, par. 2, A. G. O., Washington, D. C., November 5, 1890.

La Garde, Louis A., Captain and Assistant Surgeon. Detailed as member of board for duty in connection with the World's Columbian Exposition, and will report by letter to Major Clifton Comly, Ordnance Department, member of the board of control and management of the Government exhibit to represent the War Department. S. O. 260, par. 1, A. G. O., Washington, D. C., November 6, 1890.

Bache, Dallas, Lieutenant Colonel and Surgeon, Medical Director Department of the Platte. Granted leave of absence for one month. S. O. 82, par. 6, Department of the Platte, Omaha, Neb., November 1, 1890.

WAKEMAN, WILLIAM J., Captain and Assistant Surgeon. Relieved from duty at Fort Bidwell, Cal., to take effect on the final discontinuance of that post, and will then report in person to the commanding officer at Fort Huashusa, Ariz. Ter., for duty at that station. S. O. 254, par. 12, A. G. O., Washington, D. C., October 30, 1890.

ARTHUR, WILLIAM H., Captain and Assistant Surgeon. Relieved from duty at Fort Bayard, N. M., and will report in person to the commanding officer at Fort Grant, Ariz. Ter., for duty at that post, relieving First Lieutenant William B. Banister, Assistant Surgeon. S. O. 254, par. 12, A. G. O., Washington, D. C., October 30, 1890.

BANISTER, WILLIAM B., First Lieutenant and Assistant Surgeon. On being relieved by Captain Arthur, will repair to this city and report for duty to the commanding officer at Washington Barracks, District of Columbia. S. O. 254, par. 12, A. G. O., Washington, D. C., October 30, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 8, 1890.

EDGAR, J. M., Passed Assistant Surgeon. Ordered to the San Francisco, November 10, 1890.

SPRATLING, L. W., Assistant Surgeon. Ordered to the San Francisco, November 10, 1890.

WHITE, CHARLES H., Medical Inspector. Ordered to the San Francisco, November 10, 1890.

SCOTT, HORACE B., Passed Assistant Surgeon. Placed on the retired list October 31, 1890.

ASHBRIDGE, RICHARD, Passed Assistant Surgeon. Surveyed and sent to hospital, Philadelphia, Pa.

KENNEDY, R. M., Assistant Surgeon. Detached from Navy Yard, League Island, and ordered to the Training-ship Richmond.

ATLEE, L. W., Assistant Surgeon. Ordered to the Navy Yard, League Island, Pa.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 8, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	27	10
Scarlet fever	58	11
Cerebro-spinal meningitis	3	3
Measles	131	13
Diphtheria	81	19
Small-pox	1	0
Varicella	3	0
Pertussis	3	0

Are Vaginal Injections in Labor Useful?—Drs. Glockner and Keller have recorded some interesting statistics observed in an obstetrical clinic in Berlin, bearing upon the question of antiseptic injections during and after labor. The cases taken were all of a normal character, their number being between four hundred and five hundred. These were divided into two series. In the first series the external genitals were cleansed, at the commencement of the labor, with soap and a solution of perchloride of mercury, and a vaginal injection given of ordinary water, and sometimes a similar injection after the labor was over. In the second series the external genitals were cleansed as before, but no injections were given. In both series the hands of the accoucheur were cleansed with a solution of corrosive sublimate of the strength of 1 to 1,000. There was no case of serious puerperal disturbance in either group. The cases of slight and transitory fever numbered six per cent. in the first group and only 0.84 per cent. in the second group. From this it would appear that intra-vaginal injections of antiseptic fluid, or even of plain water, in ordinary labors are quite useless, if not worse than useless. As regards the external ablution, however necessary in the case of the class of women who are attended in the obstetric departments of German hospitals, we cannot recommend English accoucheurs to adopt the practice. It is not unlikely that English women would resent it as an impertinent interference.—*Hospital Gazette.*

Gastro-Hysteropexy.—M. Pozzi performs hysterorrhaphy after certain modifications introduced by himself. The uterus having been exposed and brought forward till it touches the abdominal wound, a continuous silk suture is passed through the posterior sheath of the rectus close to its cut edge on the left side, the peritoneum, and the uterus in the middle line, and hence to the peritoneum and sheath of the rectus on the right side of the wound. The uterus is transfixed three times in this manner, the needle passing a short distance under the serous coat, further in the uppermost than in the lower points of transfixion. The suture is finally tied and cut short. The more superficial layers of the abdominal wound are sutured separately. M. Pozzi described two cases of retroflexed uterus bound down by adhesion where this operation was performed. The first case was a complete success. Alexander's operation had been already attempted without giving relief. In the second there was suppuration of the lower part of the wound, which the operator attributed to the fact that the silk suture had not been sufficiently boiled. The uterus in each case remained firmly fixed to the parietes. M. Pozzi prefers the continuous sunken suture to the interrupted suture passed outside the integuments, and removed on about the fifteenth day after operation, as practised by Leopold, who considers that a relatively loose adhesion is sufficient.—*The British Medical Journal*, September 20, 1890.

A Warbling Girl.—A lady writing to the *British Medical Journal* says that she recently heard a young girl of fourteen years "whistle," as her people called it, but "warble" it really was, for she kept her mouth slightly open, and the lips merely trembled, the notes being formed in the throat, the centre of it working as a bird's does when singing, and the sounds produced were exactly like those of blackbirds and thrushes. She warbled several airs to pianoforte accompaniments faultlessly and most beautifully modulated; and so powerful were the notes that her grandmother, who was excessively deaf, could catch every one, without the slightest effort, in another room a little distance off; in the same room some notes were deafening, when she poured them out at the *forte* parts. She had been self-taught entirely from "whistling" to her dog and sitting in the window to "warble" to the birds.

The Number of Retail Liquor Dealers in the United States, according to the official returns of the officers of the internal revenue for the year ending May 1, 1890, was 185,868, or 1 liquor-dealer to every 275 inhabitants, on the basis of the census of 1880. In New York there was 1 retail dealer in distilled liquors to every 150 inhabitants; in New Jersey, 1 to 175; in Ohio, 1 to 230; in Pennsylvania and Massachusetts, 1 to 400; in Indiana, 1 to 325; in Delaware, 1 to 160, and in California, 1 to 75. The average in all the States which have general license laws is 1 dram-shop to 250 inhabitants. In Maine there is 1 retail dealer in distilled liquors to every 750 inhabitants; in Vermont, 1 to 820; in Iowa, 1 to 520, and in Kansas, 1 to 800.

Medical Journalism in Russia.—Dr. Zhbanoff communicates to *Vratch* some very interesting data concerning Russian medical journalism. He gives a list of all the journals that have ever been published in Russia, their programmes, names of the editors, period of existence, price, and other interesting information.

Origin.—The first medical journal appeared in 1792 under the name of *Sauktpeterburgskya Vrachelniya Vydomosti* (*St. Petersburg Medical Annals*), and existed till 1794; from 1801 till 1810 appeared 1; in the second decade, 1; in the third, 3; in the fourth, 3; in the fifth, 2; in the sixth, 7; in the seventh, 13; in the eighth, 12; in the ninth (1880–90), 38, almost fifty per cent. of all the journals that were published. The journal *Drukh Zdraviya* (*The Friend of Health*) is the first in longevity, having attained the age of thirty-seven years before it expired (1833–70).

Period of Existence.—Forty-five organs have ceased to appear, and 32 are published yet. At present, in their first year, 3 journals; in second, 6; in third, 1; in fourth, 3; in fifth, 1; in sixth, 3; in seventh, 2; in eighth, 2; in ninth, 1; in tenth, 2; in eleventh, 1; in fourteenth, 1; in sixteenth, 1; in seventeenth, 1; in twenty-fifth, 1; in twenty-eighth, 1; in thirty-third, 1; in sixty-eighth, 1. All the journals together exist 324 years, on the average 10.25 years each of them. The government journals (*Voycum Medicinski Journal*, etc., in all 3) have an average of 28.25 years; of societies, 15.75; individual enterprise, 5.64. The journals that have existed and gone had 356 years in common; average, 7.5.

Places of Publication.—In St. Petersburg, 51; Moscow, 15; Kieff, 3 (of which one was published afterward in Warsaw); in Bryansk, Vororez, Kazan, Kerch, Lipetz, Novgorod, Pyatigosk, Ryazan, Glavyansk, Tiflis, Kharkoff, and Chernigoff, 1 in each. Of the 32 existing now, 18 are published in St. Petersburg, 4 in Moscow, and 10 in other cities.

Intervals of Publication.—One journal three times a week; 1 journal twice a week; 20 journals once a week; 5 journals in two weeks; 30 journals once a month; 5 journals once in two months; 4 journals once in three months; 4 journals once in four months; 10 journals at no definite period.

Publishers.—Twelve by various governmental institutions; 17 by societies and universities; 17 by professors, and 35 individual enterprises.

Contents.—Strictly scientific, 57; popular scientific, 8; popular, 17; references, 5.

Specialties.—General medicine, 36; hygiene and popular medicine, 11; ophthalmology and water-cure, 4 each; medico-pedagogical, psychiatry, surgery, midwifery, internal diseases, therapy, pharmacy, and zemsko medicine, 2 each; dentistry, 1.

Causes of Discontinuation of Forty-nine Journals.—Change in the editorship and programme, 10; by resolution of societies, 2; lack of sympathy, 3; on account of sickness or death of editor, 5; lack of matter, 1; discharge of the editor, 1; on account of other occupations of the editor, 2; causes unknown, 25.—*Times and Register.*

Statistics of Vaccination in Germany.—Dr. D. Goldschmidt has lately published some statistics as to the effects of vaccination that speak for themselves with an eloquence which makes comment superfluous. The figures are given on the authority of the Berlin Health Office, which in 1888 and 1889 was ordered by the Reichsrath to collect facts on the subject. The death-rate from small-pox in Prussia and Austria from 1860 to 1869, when vaccination was not compulsory, was 33.84 and 33.23 respectively per 100,000 inhabitants; in England during the same period it was 19.98. In 1875 vaccination and revaccination were made compulsory in Prussia, and between that year and 1884 the death rate from small pox fell to 2.23 per 100,000. During the same period it was 6.61 in England, where vaccination alone was compulsory, and 61.64 in Austria, where it was left to "local option." In Bavaria, where both vaccination and revaccination have been compulsory since 1875, the death-rate from small pox between that year and 1884 has been 1.11 per 100.000, the corresponding ratio for Belgium, where vaccination is optional, being 44.36 during these ten years. Equally striking results are got by comparing the small-pox mortality of some large European cities during the same period. Taking first towns where vaccination is optional, we find that the average death-rate per 100,000 inhabitants was 165.437 in Prague, 84.373 in Vienna, and 28.954 in Paris. In London, under compulsory vaccination, the corresponding ratio was 25.500. When we come to the towns where both vaccination and revaccination are compulsory, the difference is striking. Thus the small-pox death-rate per 100,000 was only 1.482 at Dresden, 1.614 at Breslau, and 1.687 at Berlin. In 1886 only 193 persons died of small-pox in the whole of Germany, being at the rate of 0.4 per 100,000, while in Paris alone there were 218 deaths from the disease in that year. Small-pox has all but disappeared from the Prussian army, only one man having died of it from 1876 to 1885. In the Austrian army, where the revaccination of recruits is not insisted on, the average number of deaths from small-pox is 52 a year. The following figures, drawn from the books of a few German hospitals, may also be commended to the earnest attention of antivaccinators; they show the proportion of deaths among small-pox patients during the great small-pox epidemic of 1870–71, according as they were unvaccinated, vaccinated, or revaccinated. Of patients belonging to the first of these categories eighty per cent. died at Munster, seventy per cent. at Posen, and fifty-four, seventy, sixty-six, and eighty-one per cent. respectively at four Berlin hospitals. Of the vaccinated patients thirteen per cent. died at Munster, twelve per cent. at Posen, and thirteen, sixteen, fifteen, and fourteen per cent. in the four Berlin hospitals. Among revaccinated patients the corresponding percentages were as follows: Munster, 0; Posen, 2; Berlin hospitals, 0, 4. 9, 9, respectively. In Bavaria in 1882 it was found that of the whole number of small-pox patients only 14.6 per cent. were vaccinated and 5.8 revaccinated.—*British Medical Journal*, June 14 1890.

To Detect Fecal Matter in Drinking Water Griess recommends a feebly alkaline solution of para-diazobenzol-sulphuric acid, which, with water contaminated as indicated, will produce a yellow discoloration within five minutes. Try it on the old well next summer.

Removal of Iron Rod from Bladder.—A patient was trying to use a solid metallic rod, five inches long, and the diameter of No. 10 catheter in the place of the ordinary bougie, for the treatment of a stricture. He was in the habit of inserting the rod into the urethra at bedtime, and allowing it to remain during the night, when he would remove it by means of a "string" attached to a "hook" in one end of the rod. On the morning of the 23d September, while he was attempting to remove the rod, "the string broke," and the rod passed into the bladder, which was partly filled with urine. He remained in this condition twenty-four hours before medical aid was called. Dr. A. C. Winn, of Santa Cruz, Cal., was called to attend the case, and, with the assistance of Drs. Doyle and McGuire, succeeded in dilating the urethra, and with a pair of urethral forceps he was able to grasp one end of the body, which was just at the mouth of the bladder, and removed it without much difficulty. The patient was greatly relieved, and made a very good recovery. Nothing in the way of an anæsthetic was used except a few drops of a ten per cent. solution of cocaine injected into the urethra, and a hypodermic injection of morphine and atropia a few minutes before the operation commenced. Taking the history of the case, the nature of the foreign body, the manner of its introduction into the bladder, and the way in which it was removed, it is certainly a remarkable one, and one that seldom happens.

International Congress of Hygiene.—The honorable secretaries of the Committee of Organization of the Seventh International Congress of Hygiene and Demography, call attention to the fact that this congress will be held in London during the week beginning August 10, 1891. The governments of all countries and municipalities, and all public health authorities, universities, colleges, and societies occupied in the study of the sciences more or less immediately connected with hygiene, are invited to co-operate and appoint delegates to represent them at the congress. The Prince of Wales will preside. A Committee of Organization has been formed, of which Sir Douglas Galton is chairman, and Professor W. H. Corfield and Mr. Shirley F. Murphy are honorary secretaries. An exhibition of articles of hygienic interest will be held in connection with the congress. The last of these congresses was held in Vienna in 1887, and was attended by over two thousand persons, and it is expected that the London meeting will be one of great magnitude and importance. Very respectfully, JOHN S. BILLINGS, M.D., Member of the International Permanent Committee, Washington, D. C.

The Worship of Æsculapius.—The admirable fooling of the Plutus of Aristophanes brings vividly before us the customs of the Æsculapius worship of Athens, the sleeping of the patients in the temple of the god, and his appearance in the dead of night to counsel and restore them. Some modern writers have tried to show that the real healing power of the temples of Æsculapius lay in the salubrious sites and gushing fountains, in the daily walks in their shady arcades, and the freedom from business and dissipation which they offered. Such a view is quite in accord with the materialism which always prevails in the great medical schools. But it is not in accordance with the facts. There were medical schools in antiquity, of which writings like those of Celsus give us a high opinion, and they probably looked on the temples of Æsculapius in much the same way in which modern physicians look upon hypnotism and faith-healing. The fact appears to be that the priests of Æsculapius had no competent knowledge of medicine; and the site of the temple, at Athens at least, was anything but salubrious, hidden under the rock and exposed to the full power of the sun. The throng which filled the halls of the god was a proof that the heart of the people was in revolt against the materialism of the profession. People came to Æsculapius to be healed because they preferred divine to human aid; perhaps because human aid had done all it could for them without result. And, probably, the great majority went to sleep in the temple of the god with a strong faith that he would really take compassion on them, and either work a direct miracle on their diseased members, or, at least, give them advice by which they might profit. That faith in the votaries should be sometimes met by imposture on the part of the priests was natural. As to the relative proportions in the whole cult of belief and of imposture, we have insufficient means of judging, in spite of numerous recent documents recovered from Epidaurus, the chief seat in Greece proper of the worship of Æsculapius. These documents record a number of miraculous cures, some even of an extravagant description, but they give us but little idea of the manner in which they were brought about. The existing remains at Athens help us to reconstruct the daily life of the patients of Æsculapius, but do not offer us any material for the history of ancient medicine. Even the models of limbs which were commonly dedicated to the god by those who had been cured, and which were as common in Greek temples as they still are in the churches of Belgium and Italy, have in this case not been found. The worship of Æsculapius belongs in Greece mainly to the later age, when the decay of civic life and practical politics had left men more at leisure to study the symptoms of their own complaints, and when the people had so far fallen away from their allegiance to the great civic deities as to be ready to devote themselves to cults of a newer kind and more marked by actuality.—*The Quarterly Review.*

Some Views on Rickets.—In a recent paper Dr. Quisling considers the subject of rickets, holding that there are at least two varieties of the disease, and that at present it is not scientifically established that acute rachitis and the common chronic form have the least to do with each other; that for many so-called cases of acute rachitis the proper name would be surbutus infantilis, for others ostitis, periostitis, or osteomyelitis. He has seldom observed fœtal rickets, but congenital rickets was found in from three to ten per cent. of all new-born children. Rickets generally begins between the sixth and eighteenth months; after the third year circumstances are unfavorable for the onset and development of rickets. As ordinary symptoms of the earliest period, he mentions pallor, sweats, restlessness, spasm of the glottis, disturbances of digestion. In the second stage are found wasting, sensitiveness to touch, anomalies of dentition, respiratory diseases. In the third stage appear alterations in the consistence and form of the bones, and often swelling of the veins and spleen. The extension of the disease to almost all organs points clearly to the hypothesis of a constitutional disease, which must be put in the general class of chronic inflammations, and which arises through a cause of probably irritative nature, acting directly through the blood or indirectly through the nervous system. He is sceptical on the question of hereditary rickets, and finds no material to indicate syphilis as a cause. On the other hand, he finds a want of fresh air the only acceptable explanation of two facts much too little considered, viz., the geographical distribution of rickets, and its prevalence in certain seasons of the year. He is less positive as to the harmfulness of digestive disturbances. It is true the contingent of breast-fed children in the first year of life amounts to fifty-one per cent. compared with seventy-six per cent. of bottle-fed children; still the difference of twenty-five per cent. may have other possible causes.

Potassium Nitrate in Intermittent Fever.—Dr. J. D. Hunter writes, in the *North Carolina Medical Journal*, that he continues to have remarkable success in the treatment of intermittent fever with nitre. He says that he has treated more than two hundred cases of chronic chills of malarial origin, from a few months to years standing; many complicated with enlargement of the liver and spleen, dropsy, jaundice, etc., all more or less emaciated and anæmic. Nearly every case was cured with a single dose of nitrate of potassium. From two to fifteen grains of the salt, according to age, dissolved in a half ounce of water, administered just prior to the chill or during its continuance, did not only abort or arrest the chill, but effectually prevented its recurrence. In order to test the value of the remedy, Dr. Hunter employed no subsequent treatment, but left the restoration to health (which was in nearly every instance rapid and satisfactory) to the *vis medicatrix naturæ*. He is fully assured that from two to fifteen grains of potassium nitrate will usually abort or arrest a chill arising from any cause. A large dose, however, is not well borne by the stomach, and frequently, in the writer's hands, caused most alarming and distressful symptoms, by producing a prolonged depression of the heart's action.

The Duration of Life in the Medical Profession.—It is calculated, on the basis of statistics, that the average duration of the lives of medical men in Prussia, from the end of the thirtieth year onward, is somewhat below that of the total male population of the country, though the latter includes a large number of decrepit and diseased persons, such as the nature of the medical profession excludes.

AN EXPERIMENTAL STUDY OF PREVENTIVE INOCULATION IN TUBERCULOSIS.

BY E. L. TRUDEAU, M.D.,

SARANAC LAKE, N. Y.

THE idea of applying preventive inoculation to tuberculosis is not a new one. Ever since it was first demonstrated that artificial immunity against an acute infectious disease could be conferred by this method the possibility of its successful application to tuberculosis has occupied the minds of investigators.

Dr. Falk, in 1883, in a communication to the Medical Society of Berlin, described his attempts at preventive inoculation for this disease by means of tubercular virus attenuated by contact with putrefying material. A. Marfan,[1] in 1886, suggested the possibility of attaining success by this method from clinical facts he had observed relating to the protective influence of healed lupus and scrofulous glands. H. Martin,[2] in 1887, Raymond and Arthaud,[3] and others, more recently, have described their attempts and experience in this line of investigation.

The improvements made in the technique of laboratory methods and the encouraging results which have recently been obtained in protecting living animals by preventive inoculation against a number of bacterial diseases has prompted investigators to renewed studies in this direction.

If we have been taught by the extended researches of the past years the difficulties which must beset the direct destruction of the tubercle bacillus in the tissues of man and animals by germicidal methods, we have also learned that a living organism possesses many and mysterious powers of resistance, that the margin between susceptibility and immunity, whether purely biological or chemical, is often a very narrow one, and that the most promise at present seems to lie in the study of nature's laws of immunity and in learning how far we may influence and imitate these. Immunity from disease being a part of the unsealed riddle of life itself, the study of its mechanism has ever been beset with apparently unsurmountable difficulties, and an exact knowledge of its laws as yet escapes us. Immunity from microbic diseases is usually a natural attribute of the living organism in which it resides, but we now know that, so far as certain infectious maladies are concerned, it may be conferred artificially, and this may be said to be true of variola and hydrophobia in man (if this be a microbic disease), and of anthrax, chicken cholera, and some forms of septicæmia and hog cholera in animals.

In tuberculosis mere physical vigor is no doubt a prominent element in the mechanism of immunity; indeed, it is the only element we can as yet seize, clinical observation and experimental research bearing ample evidence to the favorable influence which all external conditions of evironment tending to increase bodily vigor invariably exercise over the prevention and course of the disease, and to the close association which exists between depressed vitality, with its cellular degeneracy, and tubercular infection.

[1] Archives générales de Médecine, April and May, 1886.
[2] Études experimentales de la Tuberculose, 2me Fas., 1887.
[3] Ibid., 1er Fas., 1887.

It is not, however, the only element, for it is in the prime and vigor of adult life that the disease displays its greatest activity, and strong men, whose tissues are apparently well nourished, at least so far as we can judge by the external appearance, frequently succumb to acute tuberculosis in a short time, while many debilitated and delicate individuals, living under the worst possible hygienic surroundings and whose nutrition is constantly at the lowest ebb, never suffer from this disease. There appears to be, therefore, over and above the element of physical vigor, a natural immunity against natural means of infection in tuberculosis, as in all other infectious diseases—an immunity possessed to a different degree by different individuals and species of animals, and which is quite sufficient for their protection, no matter at how low an ebb their physical vigor may chance to be. Whether we believe that immunity is due to the germicidal power of blood-serum, to the phagocytic activity of the cells, to purely chemical reactions intimately connected with the biological life of the tissues, to an unsusceptibility of the nerve centres to the poisonous products of the microbes, to a combination of these elements, or to some factor as yet unknown, it is evident that the margin between immunity and susceptibility is a very narrow one at first, that some trifling chemical or biological variation in the tissues is capable of turning the scales for or against infection, and some hope would seem to lie in the possibility of artificially inducing this condition of resistance in them. Acquired immunity is established naturally by a previous attack, artificially by some form of inoculation. From a mass of more or less contradictory testimony regarding immunity by inoculation we may seize this one prominent fact, namely, that there resides in the living organism a certain power of habituation to noxious influences, one of the simplest expressions of which is to be found in the tolerance to poisonous drugs which may be brought about by graded doses, and the most complex in the protection afforded by vaccination. In variola, probably in hydrophobia, and in the group of diseases of animals against which protection can be artificially conferred, an immunity as complete, though not as lasting, as that established by a previous attack may be obtained by some form of inoculation. All successful methods of inoculation so far rest upon the application of what, owing to our ignorance, we can as yet only designate in a vague way, as the law of habituation, the virus which gives protection being generally either an attenuation or a modification of the same which causes the disease. In one instance this artificial protection will be induced by an artificially modified or attenuated microbe; in another, apparently by the chemical and metabolic products which the growth of the virulent microbe develops. Thus, in the septicæmia of guinea-pigs [1] and in hog cholera [2] the soluble products of the microbe's life history, so far as the limited evidence at hand shows, prove an efficient protection in these animals against subsequent and repeated injection of the most virulent cultures; in chicken cholera the attenuated bacteria alone give protection, while in anthrax both the soluble products of the virulent germs and the attenuated microbe can render certain animals immune.

How universal is this law of habituation, through whose operation living beings can at will be rendered invulnerable to these deadly maladies? Is its protecting influ-

[1] Annales de l'Institut Pasteur, October 25, 1889.
[2] Medical News, September 6, 1890.

ence limited to the more active or rapidly fatal infectious diseases, or may it extend as well to the more chronic forms, such for example, as tuberculosis? Certainly there has not in the clinical history of tuberculosis seemed to be much to foster the hope that any method of preventive inoculation is likely to be successfully applied to this disease; but some encouragement to investigation in this line may be derived from the possible universality of the law of adaptation to noxious influences generally, from the brilliant achievements of the past years in the field of vaccination, and from the recent improvements in methods of conferring artificial protection.

Can the tubercle bacillus, or the soluble products of its life history, when treated according to the teachings of modern science, be made to confer any degree of immunity against this disease? To collect and present some evidence on this point has been the object of the present study.

Modern methods of protective inoculation aim at obtaining virus mainly in two ways: 1. By securing the soluble products of the microbe's life history freed from living germs. 2. By the production of an attenuated germ.

In the first series of experiments a non-living complex chemical substance was introduced as protecting agent; in the second series, a living but attenuated germ.

Series I. Inoculation of Chemical Substances.—In this set of experiments three forms of material were made use of: 1st, surface cultures of tubercle bacilli, which through the influence of heat and light were dead and refused to grow on the usual culture media; 2d, liquid cultures of tubercle bacilli grown for a month and then sterilized by heat; 3d, liquid cultures of tubercle bacilli freed from living germs by filtration through a porcelain filter. These substances were injected subcutaneously into fifteen rabbits divided into three equal lots.

Lot 1. Dead Surface Cultures.—Five rabbits received on three occasions, at intervals of four days, subcutaneously, 4 c.c. of dead surface culture suspended in distilled water in sufficient amount to make an opaque turbid emulsion. No disturbance of temperature or health followed; no abscess or irritation at the site of injection was noted; the animals were kept for six or seven weeks, when they were injected in the lung with ½ c.c. of slightly milky emulsion of living virulent tubercle bacilli.

Lot 2. Sterilized Liquid Cultures.—Having grown pure cultures of tubercle bacilli in glycerine-peptone-bouillon for a month and proved their purity microscopically, the flask containing them is steamed for an hour. The liquid, in which are suspended the dead germs, is then cooled and injected, with antiseptic precautions, into the subcutaneous tissue of five rabbits, to the amount of 6 c.c. for each animal. These injections are repeated on five occasions, at intervals of five days, increasing gradually the amount to 12 c.c. to each animal. The subcutaneous introduction of this liquid was followed by a marked rise of temperature and by a trifling, but temporary, irritation at the site of puncture; not a single abscess occurred, and the rabbits, when inoculated with virulent culture four weeks from the last vaccination, were apparently in good condition.

Lot 3. Filtered Cultures.—Having grown pure cultures of tubercle bacilli in glycerine peptone-bouillon for a month, and proved their purity microscopically, the entire contents of the flask is filtered with very slight pressure through a porcelain Pasteur filter. The clear filtrate proved free from germs, as shown when planted in fresh bouillon tubes, and two animals injected with this liquid and killed three months later presented no tubercular lesions. Injections of this filtered fluid, in the same amounts and at the same intervals as in the preceding lot of animals, were made in five rabbits. These gave rise in the animals to the same elevation of temperature which was noted in Lot 2, injected with sterilized liquid cultures. The temperature, usually about 102 ½° to 102 ½° F. at the time of the injection, falls a little during the first hour, then rises shortly until the fifth hour to between 106° and 107° F. It maintains itself at this high point until the eighth or tenth hour, when it slowly returns to normal. Control rabbits, however, injected with the same quantity of fresh glycerine-peptone-bouillon show a rise nearly equal to the one described, and which presents an almost identical curve. This, coupled with the fact that large amounts of fresh surface cultures when mixed with sterilized water and injected subcutaneously give but a trifling rise of temperature, makes it questionable whether this high temperature may not be almost entirely due to the peptones and salts contained in the bouillon. No irritation occurred at the site of puncture, which was done antiseptically, though in the last injection 12 c.c. of the fluid were introduced at a time. No abscess and no permanent toxic symptoms followed, and the animals, which had been kept over two weeks after the last injection, were in excellent health when, together with their mates, they submitted to the final inoculation with fresh cultures. On the same day (February 22d) all these rabbits, Lots 1, 2, 3, together with five fresh ones as controls, were inoculated in the right lung with ½ c.c. each of a suspension of tubercle bacilli in bouillon. Two months later the controls were killed, and the autopsies of the other animals, Lots 1, 2, 3, followed as rapidly as possible, extending over a period of less than two weeks. The results are briefly told: All the rabbits are more or less tubercular; the lesions of those in whom this preventive inoculation was practised differ from those observed in the controls but little, except that in the rabbits previously injected with the filtered cultures (Lot 2) the disease is somewhat more advanced. The experiment relating to this set of animals was therefore repeated in precisely the same way as before, except that the interval between the last preventive inoculation and the virulent inoculation was only three days. Four animals were used. Two months later, the two rabbits who had undergone the protective treatment were found to bear tubercular lesions appreciably farther advanced than the controls.

The second set of experiments relate to preventive inoculation with a living but attenuated microbe. Our knowledge of the conditions necessary to either diminish or increase the natural virulence of the tubercle bacillus, is still very fragmentary. Roux, Nocard, Yersin, and all the experimenters of Pasteur's school have stated that cultivation in glycerinated media so increases the virulence of Koch's bacillus that a germ is thereby obtained capable, upon intravenous injection, of killing rabbits with great regularity in eighteen to twenty-four days, the animals presenting a peculiar form of septic tuberculosis. I have never been able to produce in the ordinary rabbit for sale in our markets here the type of disease these investigators so ably describe, nor have I noted any marked increase in the pathogenic properties of the tubercle bacillus when it is cultivated in glycerinated media. Cultures which I have been able to make directly from the lesions of acute miliary tuberculosis in the human subject have not differed to any appreciable extent in their effects on animals from tubercle bacilli obtained from other sources. All attempts on my part at systematic attenuation of tubercle bacilli by placing them in an unfavorable environment have proved nearly as unsuccessful. Under what manipulation I have so far brought to bear on them individual cultures have been often so nearly killed as to lose much of their pathogenic power, but this could not be regulated with any degree of certainty, and failed to be reproduced with any regularity in subsequent generations; either the microbes would refuse to grow entirely, or the subsequent plants which grew soon regained their usual virulence.

Many pathogenic microbes when transferred from a parasitic to a saprophytic existence adapt themselves readily to their altered surroundings, which produce in them two important changes—they grow more easily and abundantly in culture media and they lose to a greater or

less degree their power to maintain themselves in living beings, in other words, their virulence.

The tubercle bacillus, on the contrary, seems to adapt itself with some reluctance to a saprophytic existence, and is with great difficulty robbed of any degree of its virulence. My observations in this particular coincide with those made by Dr. Koch, who found that after having led an uninterrupted saprophytic existence for eight years cultures of tubercle bacilli under his observation remain the same, save for a very slight diminution of virulence. What I failed, however, to accomplish by my own efforts chance all at once put in my way and furnished me with what was apparently an attenuated tubercle bacillus. Among a large number of tubes on my thermostat, in January, 1890, I noticed that in several, all having the same origin (the lesions of a guinea-pig caused by the scrapings of an old phthisical cavity) a marked cultural variation had appeared. This I ascribed at first to contamination, but careful double staining proved the cultures to be pure. These tubes I presented, in April and May, 1890, to the New York Pathological Society and to the Association of American Physicians, describing at that time their biological peculiarities, which consisted in a well-defined and constant cultural variation and in a great diminution of natural virulence. Rabbits inoculated subcutaneously with these cultures present after four months only an indolent localized lesion at the site of injection and no visceral disease. The cheesy abscess thus caused often grows to great size and shows no tendency to open externally; as time goes on it generally loses its cheesy character, becomes gelatinous in appearance and tends often slowly to disappear, the animal still continuing free from visceral disease. Intra-pulmonary injections of small amounts produce in rabbits a localized tubercular process with little tendency to spread, or spreading very slowly in rare cases, and which is often entirely recovered from. Intravenous injection of moderate amounts of this attenuated germ gives rise to no appreciable disease, while intra-peritoneal inoculation of large quantities is usually fatal. In guinea pigs, tuberculosis running a very slow course is brought about by all the above methods of inoculation, except by subcutaneous injection, which generally results only in a localized cheesy abscess similar to that caused in rabbits, but showing a much greater tendency to open and discharge itself externally. Whether this attenuation was due to the origin of these bacilli, or to the varied conditions of their surroundings while under cultivation through many generations it is impossible at present to determine; but these constant cultural peculiarities and their enfeebled virulence seemed to warrant the assumption that the microbes in question were an attenuation of the tubercle bacillus, and these cultures were therefore used in the following experiments to produce a mild and localized form of the disease and determine whether they would afford protection against a subsequent virulent inoculation.

Series II. Experiment A. Inoculation of Living Virus.—Four guinea-pigs were injected under the skin of belly with an old liquid culture (A) of the above-described attenuated bacilli in glycerine-peptone-bouillon, and a week later again with a fresher culture (B) of a month's growth, just taken from the thermostat, where it had been grown at irregular temperatures, ranging from 34° to 44° C. Plants of both sets of cultures, A and B, in fresh bouillon, showed six weeks later abundant growth from culture B, and from culture A in only one of the three tubes planted. The animals were kept five weeks, when they appeared in excellent condition, but all presented a small unopened abscess at the site of the second preventive inoculation, without any enlargement of the lymphatic glands. Two of them (Lot A) were then, together with two fresh animals as controls (Lot B), injected under the skin of belly with ½ c.c. of a virulent culture of the tubercle bacillus suspended in distilled water, while the remaining two animals (Lot C), which had been subjected to the protective treatment alone, were kept to determine the effects of the attenuated culture. All the animals were killed six weeks later. The results were as follows:

Lot C (simply subjected to protective treatment).—Both guinea-pigs present a small ulceration where the attenuated culture has been injected; in the first animal the spleen is a little enlarged and two gray tubercles are visible in the right lung; in the second animal all the organs are perfectly normal.

Lot B, Controls.—Both animals are markedly tubercular and present ulcerated cheesy abscesses, cheesy inguinal, mesenteric, and bronchial glands, very large tubercular spleens, and young tubercles scattered through liver and lungs.

Lot A.—Having undergone preventive and subsequent virulent inoculation. Both animals are profoundly tubercular, perhaps a trifle more so than the controls whose autopsies are briefly recorded above.

Series II. Experiment B.—This experiment was a repetition of the last one, only the protective inoculations were made with surface cultures of the attenuated bacillus grown on glycerine-peptone-agar, instead of liquid cultures, as in experiment A, Series II. The first preventive inoculation was made on six guinea-pigs with an old surface culture four months out of thermostat; the second, a week later, which a fresh one grown at irregular temperatures from 34° to 44° C., and whose viability was proved by plants on fresh culture media. After having been kept five weeks the animals showed very trifling indurated spots at the site of injection and were apparently in good health. Two of them, Lot A, were kept to control the preventive inoculation, and the four others, lot B, together with four fresh controls, Lot C, were injected under the skin of abdomen with a suspension of virulent tubercle bacilli in distilled water. Six weeks later all the animals were killed.

Results.—Lot A. Simply subjected to protective inoculation. One animal presents a small open ulceration at the site of vaccination, with one slightly enlarged inguinal gland; all the organs in both animals are perfectly healthy.

Controls, Lot B. All markedly tubercular, cheesy abscesses, cheesy glands, spleen, liver, and lungs riddled with tubercle.

Lot C. (injected first with attenuated and subsequently with virulent cultures). All tubercular; one only moderate, the other three are more extensively diseased than the controls.

Series II. Experiment C.—This experiment was merely a repetition of the last two, A and B, Series II., and was made for purposes of confirmation and control. Sixteen rabbits were used, ten (Lot A) were injected twice, at intervals of seven days, with a fresh surface culture of the attenuated bacillus grown at a constant temperature of 37° C. At the expiration of four weeks they presented prominent abscesses at the site of injection, but were otherwise in good condition. They were then, together with six controls, inoculated in the vein of the ear with 1 c.c. of virulent tubercle bacilli suspended in distilled water. Eight weeks later they were all killed within a few days of each other. The animals who had undergone preventive inoculation (Lot A) all had large indolent abscesses at site of injection with the attenuated material. When killed, all the rabbits present the lesions of miliary tuberculosis of the lungs in varying stages of development; the other organs are sound. Both lots are about equally tubercular.

Summary of Experiments.—*Results:* In Series I. preventive inoculation of the non-living chemical products of the life history of the tubercle bacillus failed, when applied as above described, to afford any protection against subsequent infection with virulent living tubercle bacilli.

In Series II. preventive inoculation with an attenuated but living germ, capable of producing in most cases only an indolent and localized tubercular process at the site of injection, failed to protect against subsequent

inoculations with virulent tubercle bacilli. No immunity seems to have been conferred by a saturation of the system which the chemical substances evolved by the microbes during their growth in artificial culture media, or by the production of a mild form of the disease. It must not be forgotten, however, that the methods of preventive inoculation which have formed the groundwork of this study are merely tentative and in a field in which we can as yet but grope our way. They may seem crude even now, and in the light of our rapidly advancing knowledge on this subject they will soon appear even more so than at present. Nevertheless, merely as a biological study of the tubercle bacillus these observations seem perhaps worthy of record, and we may, in spite of the unpromising evidence which they have brought forth, turn to the brilliant announcements recently published with a strong hope that the resources of foreign laboratories or the individual efforts of some earnest worker are about to solve the problem of protective inoculation for this disease, even if the genius of Koch, reaching out along new lines, has not already succeeded in producing a specific treatment for the cure of tuberculosis.

EXPLORATORY PUNCTURE OF THE FEMALE PELVIC ORGANS.

A Diagnostic Study.[1]

By GEORGE M. EDEBOHLS, A.M., M.D.,

GYNECOLOGIST TO ST. FRANCIS HOSPITAL, NEW YORK.

For the past two years I have systematically practised exploratory puncture as an aid in the diagnosis of those diseases of the female pelvic organs which are attended with comparatively slight increase in size of the parts involved. In these cases we are but too often forced to content ourselves with the diagnosis of a "mass," to the right or left of, anterior or posterior to, the uterus. This diagnosis of a "mass" is thoroughly unscientific and unworthy of progressive gynecology, which demands that it shall become less and less frequent. For my own part, I confess that I have never made it, or announced it, without a feeling of humiliation at not being able to do better.

It was this feeling of humiliation and discontent which led to the attempt, at first in isolated instances, to reach a more definite diagnosis by exploratory puncture of the "mass." Subsequently, encouraged by one or two gratifying results, I elaborated a technique or method of exploratory puncture which I have since systematically practised in all cases where, without it, a positive diagnosis could not be reached. While it has often failed to throw any further light upon the case, it has nearly as often been of signal service in elucidating the diagnosis. It has determined me to the performance of laparotomy where, without it, I could not have made up my mind to the necessity of the operation. On the other hand, it has led me to decline operative interference in cases where, without the knowledge conveyed by it, I, in common with most of my brother gynecologists, would have recognized clearly the indications for abdominal section. In other words, it has in a number of instances served to give greater precision to the indications for and against laparotomy.

Scope of the Paper.—This paper, let it be distinctly understood from the outset, does not embrace the subject of the diagnosis of the larger tumors of the abdomen, whether originating from the pelvic or abdominal organs. It concerns itself *solely* with the differential diagnosis of slight enlargements, or "masses," which are either situated entirely within the pelvis proper, or, originating there, project but slightly above the brim of the true pelvis into the abdomen, and which are clearly recognizable only by combined abdominal and vaginal touch.

[1] Read before the Section on Obstetrics and Gynecology, New York Academy of Medicine, October 23, 1890.

Methods of Exploratory Puncture.—Before proceeding to describe my own method of exploratory puncture, I should like to be permitted a few words and a few criticisms upon the various methods in common use. These methods may be classified as: 1. Abdominal exploratory puncture. 2. Vaginal exploratory puncture. 3. Rectal exploratory puncture.

To abdominal exploratory puncture there can be no valid objection when the diseased mass lies close up against the anterior abdominal wall. But this condition is quite exceptional. I have only met it three or four times within the past two years in the class of cases we are at present considering. When a small mass lies at some depth in the pelvis, say to one side or other of the uterine cornua, and is perhaps movable, it will be a lucky thrust which will succeed in landing the point of the needle safely in its centre. In such instances there is no certainty and accuracy in the method as ordinarily practised, and it cannot be relied upon.

This same objection, together with some others, applies also to puncture made from the vagina. The vaginal method should be limited entirely to puncture of effusions or tumors distending Douglas' sac, or bulging well into the vagina, if situated laterally or anteriorly. It is practised with or without the use of the speculum. Let us take, again, the instance of a small "mass" situated high up alongside of the uterine body. If the speculum be used, the instrument will be in the way of the palpating finger, and generally prevent it from exactly locating the "mass" just previous to puncture of the latter. Without such a palpating finger for a guide, everyone of us knows how uncertain it is in what direction, or into what, we plunge our needle. Without the speculum the lesion can be better located; it is absolutely necessary, however, to retain the examining finger as a guide to the needle while puncture is being made. The presence of this finger and the absence of the speculum interfere greatly with the free and proper use of the needle.

Of the two methods of performing vaginal puncture the one dispensing with the use of the speculum is, for the class of cases we are considering, probably the better. With the speculum, be it Sims, bivalve, or cylindrical, except in cases where the tumor bulges into the vagina, you cannot be certain of really puncturing it. Without the speculum there is greater certainty of really accomplishing the puncture, but the movements of needle and syringe are greatly hampered. With both, perfect asepsis—and sufficient stress cannot be laid on this point—although not impossible, is difficult to secure, and always more or less doubtful.

In common with nearly all gynecologists I have practised vaginal puncture for many years, and still employ it in suitable cases as above indicated. These cases are, however, excluded from consideration here, as not coming properly within the limits of this paper.

Rectal exploratory puncture I would discard altogether, or limit to cases of disease of that viscus. Except in instances of neoplasms or exudates occupying the post-rectal region, I cannot conceive of the case in which vaginal puncture would not yield the same information which might be obtained by rectal puncture. I have never practised rectal puncture.

Abdominal Puncture Guided by Combined Vaginal and Rectal Touch.—I will now attempt to describe the method of exploratory puncture of the female pelvic organs as I systematically practise it. The patient is placed upon the examining-table, with the pelvis elevated or not, as may seem indicated in the particular case. The bladder should always be empty. A careful and thorough bimanual examination precedes the puncture in every instance.

This examination I am in the habit of making by passing the index-finger of the left hand into the vagina and the middle finger of the same hand into the rectum. The diseased structures are palpated between these two fingers and the fingers of the right hand placed upon the abdo-

men. More positive information can be gained in this way than by the combined abdominal and vaginal touch alone. The perineum can be carried upward, to an average extent of about an inch, upon the web or bridge between the rectal and vaginal fingers, enabling the finger in the rectum to palpate the entire posterior surface of a normal sized uterus, and to reach well up into the region of the tubes and ovaries.

The examiner must feel satisfied that he has gained all the information that a thorough examination can be made to yield. If this is impossible without an anæsthetic, then chloroform is administered. I have never administered an anæsthetic for the sole purpose of avoiding the pain of the puncture. This is comparatively slight, and generally borne without great complaint by patients, the prick of the needle as it penetrates the skin being the most painful thing about it.

If the results of the examination, be it with or without anæsthesia, are sufficient to establish a positive diagnosis in the examiner's mind, the exploratory puncture is omitted. If, however, as is often the case, a "mass" is the only thing that can be positively diagnosed; or even if, a better diagnosis being attained, tormenting doubts still assail the examiner's mind, then exploratory puncture is superadded and performed in the following manner: The skin of the lower part of the abdomen is thoroughly disinfected, with as great care as if laparotomy were contemplated. The index-finger of the left hand is carried into the vagina and the middle finger of the same hand into the rectum; or, instead of the index-finger the thumb may be passed into the vagina, and the index-finger into the rectum. I have generally preferred the former arrangement.

The ovary, tube, small tumor, or "mass" to be punctured is located by the fingers. The rectal finger, if possible, reaches around behind to the upper limits of the "mass," the vaginal finger being applied to its lower pole. The "mass," thus fixed and balanced between the finger-tips, is carried forward as far as can be done with safety toward the anterior abdominal wall.

By combined palpation a point on the anterior abdominal wall, directly over the centre of the "mass" to be punctured, is located by the carefully disinfected fingers of the right hand. At this point, wherever it may happen to be, the sterilized needle is carried perpendicularly through the abdominal wall, and all intervening tissues and organs, into the centre of the "mass."

The fingers in the vagina and rectum fix the diseased structures, control the course of the needle, and guide it into that part of the mass we desire to puncture. An assistant draws the piston, while the operator's right hand firmly grasps the barrel of the syringe, thus steadying it and the needle. This immobility of the needle and perfect asepsis are the essentials which, to my mind, guarantee the innocuousness of the procedure. Should the aspiration prove negative I never dally with the temptation to move the point of the needle forward and backward, or to advance it in a slightly different direction, but promptly withdraw it, and, if for any reason considered advisable, make an entirely new puncture.

A negative aspiration will leave the diagnosis in doubt; the withdrawal of fluid will, however, give it very great precision. In conjunction with the results of careful bimanual examination it will frequently enable us to make a very positive diagnosis, and indicate very clearly the treatment to be pursued.

I do not think I am overstating the case when I claim for this method of exploratory puncture, as compared with vaginal puncture, or with abdominal puncture as usually practised, the same superiority that is universally conceded to the method of bimanual palpation as compared with either the vaginal touch or the abdominal touch singly. It enables us to feel almost absolutely sure that we have actually punctured the diseased "mass." It is true that the "mass," though small, may be composed of various organs; may be in part fluid, in part solid. In the latter case the needle may enter the solid part, and exploratory puncture give negative results, as will be illustrated further on by one or two examples. Errors arising from such and other causes pertain to the other methods of exploratory puncture even in a greater degree, and will continue to perplex us pending the further perfection of physical diagnosis. Indeed it is as an attempted step in the direction of the latter that I would have my humble efforts here recorded considered and judged.

The Armamentarium necessary for the practice of the procedure deserves a moment's attention. It is self-evident that too coarse a needle cannot be employed with safety. On the other hand, a needle of too fine a calibre will not permit of the passage of thick fluid, and will become clogged too readily. In my investigations I have used two needles, both being of the same calibre, No. 15 steel wire gauge, though varying in length, one measures two inches, the other two and three-quarter inches from shoulder to point. The former is used to puncture the more superficial, the latter the more deeply seated "masses." I have never had occasion for a needle longer than two and three-quarter inches, although, in case of excessive fatness of the abdominal walls, the necessity for a longer needle might arise. The risk of breakage, of course, in needles of the same calibre, increases with the length; hence my preference for a needle as short as consistent with the purpose to be accomplished. Whatever, however, individual preferences may be as to length, I cannot insist too strongly that the diameter of the exploring needle shall not exceed No. 15 steel wire gauge. The syringe itself should not be too heavy and clumsy; the piston should work easily, smoothly, and evenly. The capacity of the syringe I employ is two drachms.

The Question of Danger.—Gynecologists have, as a general rule, failed to avail themselves of whatever advantage is afforded by pelvic exploratory puncture through an exaggerated dread of the danger involved in the procedure. Part of this dread is, no doubt, the outcome of the dire results that have been recorded as following tapping of abdominal tumors, especially of ovarian cysts. But it will not do to lose sight of the vast difference between puncture with and without full antiseptic precautions; between tapping with a good-sized trocar and making a puncture with a fine exploring needle. The wound made by the latter in passing through any tissue or organ immediately closes upon the withdrawal of the needle. I have repeatedly had occasion to satisfy myself at laparotomies performed immediately, as well as at varying intervals of one to fourteen days after, exploratory puncture, that my needle had gone through one or more loops of gut, or through the omentum, or through both, on its way to the tumor. No ill results followed in these cases, nor indeed in any of the more than seventy cases in which I have practised the method.

Safety, as I have before stated, depends chiefly upon two factors. The first of these is perfect asepsis; the second, immobility of the needle after the point has reached its destination and while suction is being made. By attention to the latter point we avoid tearing the organs and tissues through which the needle has passed, and thus enlarging to a dangerous extent the track of the puncture.

Some of the advantages that I have derived from exploratory puncture, as thus practised, will, perhaps, be best made obvious by the recital of a few pertinent cases. This, too, will enable each one to form an individual opinion as to the value of the method.

Suppurative Inflammation of Tubes and Ovaries.—Since January, 1889, I have removed the appendages on one or both sides, for pyosalpinx and ovarian abscess, singly or combined, in fourteen women. In all but one of these cases the diagnosis of purulent disease of the appendages was positively made before operation by exploratory puncture. In addition to these thirteen cases I diagnosticated, by the same method, pyosalpinx in several other patients who, however, declined operation.

I was able to tell all these patients, after proving the presence of pus, that they carried an abscess or collection of matter within their pelves; to state to them the dangers of this condition, and to declare, with the positiveness of full conviction, that I knew of no way of curing them except by operation. From this last general statement I must, however, except one case of double pyosalpinx in which both enlarged tubes ran outward in a straight line from the cornua of the uterus and were pervious at their uterine ends. In this case I attempted and succeeded in obtaining a cure by drainage through the uterus. In the cases in which I performed salpingo-oöphorectomy I was in a position—and the advantage of this every abdominal surgeon will be able to appreciate—to approach the operating-table with a serenity of mind and conscience based upon the positive conviction that there was no alternative, but that, as far as our present knowledge went, the operation was an absolute necessity.

In the fourteenth case I failed to find pus, although I could distinctly palpate greatly enlarged tubes, and, moreover, could feel sure that my needle had penetrated into the substance of a tubal convolution at its thickest part. I will give this case in detail.

Case I. *Double Pyosalpinx; Failure to obtain Pus by Exploratory Puncture.*—B. S——, aged twenty-two, married, never pregnant, came to me September 22, 1889, with a history of pains, lancinating and intermittent in character, in both inguinal regions, but especially severe on the right side, for three years past. Pain on sexual intercourse; no leucorrhœa; no hemorrhage.

Examination.—Uterus, tubes, and ovaries matted together into an irregular, tender mass, pretty well filling the pelvis. The outlines of the enlarged convoluted tubes can be traced running over the surface of the mass.

Exploratory puncture of a convolution of the left tube with negative results. The severity of the symptoms, however, and the futility of prolonged previous treatment, called for laparotomy, which was performed on September 30, 1889.

The uterus, both tubes and ovaries were found fused into one mass. Right tube one inch and left tube three-fourths inch in diameter; both with enormously hypertrophied walls, the lumen being scarcely enlarged above the normal. These conditions are well shown in the specimen before you. Both tubes contained pus. Right ovary contained a cyst two inches in diameter. Left ovary was the seat of a small hæmatoma, and of several small cysts. Both ovaries and tubes removed.

The failure to obtain pus on exploratory puncture was explained by the enormously hypertrophied wall and the very small calibre of the punctured tube.

The Question of Differential Diagnosis between Pyosalpinx and Ovarian Abscess.—Let us analyze somewhat more closely, for purposes of study, the thirteen cases in which the diagnosis of purulent inflammation of the appendages was made by exploratory puncture and confirmed by subsequent abdominal section. Of the thirteen, 6 were cases of double pyosalpinx with normal or nearly normal ovaries; 3 were cases of pyosalpinx and ovarian abscess of the right side, the left appendages being normal; 3 were cases of double pyosalpinx with abscess of one ovary; 1 was a case of abscess of the right ovary, with normal tubes and left ovary.

Of the 6 cases of double pyosalpinx I was able in 5 to make a positive diagnosis of the exact location of the pus; in 2 of the 5 I succeeded in doing so at the first examination. After mapping out carefully, by bimanual examination, the sausage-shaped contour of the enlarged tubes—which, when it can be distinctly made out, is, as we all know, exceedingly characteristic—I balanced the larger of the two tubes upon the rectal and vaginal fingers, thrust the exploring needle into its thickest part, and obtained pus.

In three cases the diseased organs formed with the exudate in the pelvis a perfectly indistinguishable "mass," utterly impossible at the first examination of separation into its component parts by the sense of touch. But a few days or a week of rest in bed, with hot vaginal douches, caused the peritubal, periovarian, and perituterine exudations to disappear. Then the enlarged tubes could be readily detected and punctured and a positive diagnosis of pyosalpinx was made.

In the sixth case I could not feel certain where I drew my pus from.

Case II. *Double Pyosalpinx; Rupture of Left Pyosalpinx, followed by Purulent Septic Peritonitis and Secondary Perforation of Sigmoid Flexure.*—A. P——, aged thirty-one, widow, no children. Had a miscarriage six years ago, since which time she has never been entirely well, although free from great suffering. On July 22, 1889, she fell down stairs. The fall was followed by symptoms of collapse and by severe abdominal pains which have kept her in bed ever since. Two or three days after the accident she noticed a protrusion from the vulva which would recede only on the application of great manual pressure. Fever, chilly sensations, painful micturition, and an offensive, thick, yellowish vaginal discharge were the other symptoms.

On admission, August 12, 1889, the patient was in a profoundly septic condition. During the five days following the temperature varied between 101½° and 103½° F.; pulse 110 to 130, small and feeble. Abdomen distended and sensitive to pressure over its lower half. On the right side an enlarged tube can be fairly well made out.

The region to the left of the uterus is occupied by a softish mass extending upward for two inches into the abdominal cavity. Exploratory puncture into this mass gives pus. Not being able to differentiate the component parts of the mass, I was unable to say positively from what organ or tissue the pus was derived. The clear history and signs of pelvic peritonitis, however, rendered it more then probable that a peritoneal abscess had been punctured.

Laparotomy, August 17th. Recent purulent peritonitis gluing together the abdominal and pelvic organs in a promiscuous fashion. The needle must have passed through several coils of intestine fastened by adhesions across the line of puncture. Large pus tubes, with thick walls, on either side. On the left side a peritoneal abscess containing about two hundred and fifty grammes of fetid pus. This abscess was probably punctured by the needle. It communicated by an opening one and one-half centimetre in diameter with the left pyosalpinx, by a second, somewhat smaller, opening with the upper part of the sigmoid flexure.

In the light of all the information procurable the case was interpreted as follows: The patient had probably for some years past had double pyosalpinx, not giving rise to marked symptoms. The fall caused a rupture of the left tube, followed by acute suppurative pelviperitonitis. The protrusion from the vagina noticed by the patient a few days after the fall was probably the distended cul-de sac of Douglas. A peritoneal abscess formed, which perforated the sigmoid flexure.

Case III. *Double Pyosalpinx.*—This case came twice under my care—in May, 1889, and again in December, 1889. I declined to perform laparotomy on the first occasion, although the patient had come to me with a view to operation. Eight months later I removed her ovaries and tubes. The reasons for my course will appear in the history of the case.

M. H——, aged twenty-two, single. Patient first came under my care in May, 1889, suffering from atypical uterine hemorrhages and pelvic pain. Examination reveals endometritis corporis et cervicis. Uterus slightly enlarged and perpendicular in body; freely movable. Left ovary in normal position, but enlarged to nearly thrice the normal size; right ovary normal. Either tube slightly thickened. Exploratory puncture into left ovary with negative results.

Patient was sent to me for removal of the appendages. This I declined to do for the present, and, after thorough

curetting, sent her back to her medical adviser to await further developments.

Eight months later, in December, 1889, the patient returned to me. Her symptoms had continued pretty much the same. I now made out decidedly enlarged and convoluted tubes on either side of the uterus. Both ovaries appeared normal. Exploratory puncture of left tube gives pus.

Laparotomy, January 18, 1890. Moderate adhesions. Left tube one-half inch in diameter; right tube as thick as an ordinary lead-pencil. Both contained pus. Ovaries normal. Both ovaries and tubes removed.

Patient subsequently confessed to me that her illness dated from a gonorrhœa. I thus had an opportunity to observe the gradual progress of the disease upward, invading successively the mucous membrane of the cervix, corpus, and Fallopian tubes, and resulting in double pyosalpinx.

Tubo-ovarian Abscess.—In one of the three cases of pyosalpinx and ovarian abscess of the right side, with normal or nearly normal left appendages, I was able to differentiate between ovary and tube, and to puncture the latter. In the other two I was unable to determine whether I drew the pus from the ovarian abscess or from the pyosalpinx. I subjoin notes of these two cases.

Case IV. *Puerperal Septicæmia; Tubo-ovarian Abscess of Right Side.*—A. W——, aged twenty seven, widow, was delivered of her first and only child on March 25, 1890, in a lying-in asylum of this city. The labor was difficult, necessitating the use of chloroform. She does not know whether instruments were employed.

Patient was admitted to St. Francis Hospital on April 10, 1890, suffering from well-marked puerperal septicæmia. Temperature, 103½° F. Perineum and cervix extensively lacerated. Uterus three and a half inches deep, normal in position, but limited in mobility by a large mass to its right, reaching well up into the abdominal cavity. This mass can be best felt from anterior surface of abdomen, being just beyond comfortable reach from the vagina. It is irregular, somewhat cubical in outline, three by four inches in size, its most prominent point being situated just above the level of the anterior superior spine of the ilium, and two inches within it. An exploratory puncture at this point gives thick, creamy pus at a depth of two inches from the surface. The mass was situated so high up that it might easily have been taken for a perityphlitic abscess. Not being able to differentiate tube and ovary, I could not tell from which of these organs the pus was derived.

Laparotomy, April 25th, in the presence of Professor Howard A. Kelly, of Baltimore, and Dr. H. J. Boldt, showed the tumor to be a large pyosalpinx and ovarian abscess of the right side. The appendix vermiformis was intimately adherent to its posterior surface, from which it was separated by the fingers. The thickened right tube, containing pus, coursed along the anterior aspect of the tumor. Right tube and ovary removed. Left appendages, presenting nothing abnormal, were allowed to remain. So fused was the entire mass with the right side of the uterus that it was impossible to make out a line of demarcation, and a portion of the uterine wall was removed with the diseased parts.

Case V. *Right Tubo ovarian Abscess.*—M. M——, aged twenty-two, married, no children, one miscarriage, was admitted to St. Francis Hospital, June 23, 1890. Up to her marriage, at nineteen years of age, she had been well. Shortly after marriage leucorrhœa began, and has continued ever since. Her husband had gonorrhœa in early married life. A miscarriage two years ago was followed by severe pains of a bearing-down character, and by pain and bleeding at each sexual act. Since her miscarriage has had an attack, similar to the present, about once every three months. Present attack began on June 18, 1890, with severe pains in lower abdomen, distressing bearing-down feelings, vomiting, fever, and tympanites. On admission she presented all these symptoms and was in a septic condition. Temperature, 103½° F.

On the following day examination under chloroform on account of the unbearable pain. Uterus normal in size, but crowded forward by a tumor reaching around behind it from one side to the other. The tumor was six inches long, three inches in diameter, and irregular in outline. Impossible to locate tubes or ovaries on either side. Exploratory puncture over the fundus uteri into the mass behind it proved negative. A second puncture, on the right side, one and a half inch above Poupart's ligament, yields pus. Exact derivation of pus uncertain.

Laparotomy, June 27th. Awful matting together of viscera. The omentum and small intestine, adherent over the front of the tumor, had been punctured by the needle. The right tube formed a pus-sac three and a half by one and a half inches in size. Behind it and the uterus, and adherent to both, was an abscess of the right ovary even larger than the pyosalpinx. After their removal no further induration could be felt in the pelvis. The left tube and ovary were buried behind adherent viscera, and, not being palpably enlarged, were left. I was unable to determine at the time of operation whether I had punctured the pyosalpinx or the ovarian abscess.

Of the three cases of double pyosalpinx with ovarian abscess of one side the pyosalpinx alone was diagnosticated in one case, the ovarian abscess not being detected until operation. In the other two cases the enlarged tubes were plainly mapped out by bimanual examination, and, in addition thereto, an enlargement and fixation of one ovary were recognized. Puncture was made into the latter and pus obtained. Puncture of the tube was not superadded, and a positive diagnosis of the pyosalpinx was not made in these cases, the presence of the ovarian abscess being held sufficient to indicate laparotomy, on the occasion of which the tubes would naturally be examined.

In both instances the diagnosis of ovarian abscess proved correct; curiously enough, however, the abscesses which had been diagnosticated as involving the left ovary were really situated in the right. The latter had prolapsed to the left side, and had become firmly attached there by inflammatory adhesions. I omit the histories of these three cases, as presenting nothing of interest beyond what I have just indicated.

The most recent case of tubo-ovarian abscess upon which I operated possesses features of collateral interest in connection with the subject of exploratory puncture.

Case VI. *Right Tubo-ovarian Abscess; Stenosis of the Aortic Orifice.*—M. C——, aged nineteen years, had been perfectly well up to the date of her marriage, two years ago. Since then she has suffered more or less from pelvic symptoms, the most prominent of which were leucorrhœa and pain on defecation.

Examination, October 4, 1890. Patient has a well-marked stenosis of the aortic orifice, as indicated by a harsh, systolic bruit, loudest at the base of the heart over the aortic valves. The pelvic organs being exceedingly tender, chloroform was very carefully administered, with a view to a thorough pelvic exploration. The uterus, normal in size and anteverted, is pushed slightly to left and forward by a small mass occupying its latero-posterior aspect on the right side. This mass is formed of the right tube and ovary, is about the size of corpus uteri, and on exploratory puncture is found to contain pus.

At this stage of the examination patient became deeply cyanosed and stopped breathing. The anæsthetic had already been withdrawn, and restorative measures were at once applied. After several moments of anxious suspense the patient resumed breathing and the cyanosis gradually disappeared. It was felt, however, that she had had a narrow escape.

On the following day I informed the patient of the fact that she was a sufferer from organic cardiac disease, and of the incident connected with the examination under anæsthesia. I imparted to her my diagnosis of her case, and that I knew of no way of curing her except by operation. The latter, however, I was not very anxious to under-

take, owing to the necessity of anæsthesia. I informed her frankly that, in addition to the ordinary dangers of the operation itself, she would run the risk of death on the table from heart disease. After a full day's consideration of the matter she declared, much against my expectations, that she was willing to take all risks, and requested me to perform the operation. Had I not been absolutely certain, beyond all peradventure, of my diagnosis of tubo-ovarian abscess—a certainty based upon the results of exploratory puncture—I would have refused to operate, at least for the present, under any circumstances.

The ovarian abscess and pyosalpinx herewith presented for your inspection were removed by laparotomy October 7, 1890. Ether was used as an anæsthetic, I need scarcely add in scant amount, and the operation was completed without accident.

Recovery was interrupted by an attack of acute pericarditis, which caused me considerable anxiety from the fourth to the ninth day, when it subsided. Since then progress toward convalescence has been disturbed only by an attack of acute general urticaria and the patient is now out of danger.

Ovarian Abscess.—I will report in detail a case of abscess of the right ovary, with normal right tube and left appendages. It is of interest because the palpable changes in the pelvis were so slight, almost indiscernible, that without the results of explorative puncture to indicate it I should not have considered laparotomy justifiable, and should have most emphatically refused to perform the operation.

CASE VII. *Small Abscess of Right Ovary, with Tubes and Left Ovary Normal.*—A. K——, aged thirty, married, one child; was admitted to St. Francis Hospital, May 10, 1889. Patient's history dates back two years, and began with a sudden sharp pain in right hip and right lower abdomen. Since then menstruation, before painless, has been very painful, although regular and otherwise unchanged. For six months past, bearing down pains, burning sensation over hip, and shooting pains in right side, decidedly increased by motion. No leucorrhœa.

Examination under chloroform, patient being quite fleshy. Slight endometritis and hyperplasia of cervix and corpus. Left appendages and right tube normal. On right side, high up as the fingers can reach from vagina and rectum, above pelvic brim, an induration about one and a half inch in diameter can be made out, immovably attached to the posterior abdominal parietes. Exploratory puncture of this induration gives pus. Diagnosis, ovarian abscess of right side.

Laparotomy, May 30, 1889. Both tubes and left ovary perfectly normal. Right ovary embedded in multiform adhesions to all surrounding viscera. After exposing the ovary an attempt was made to separate it by tearing its posterior adhesions. In doing so, it ruptured and discharged its entire contents, not quite two drachms of pus, into the abdominal cavity. The diseased ovary was removed with the right tube. Left tube and ovary were not disturbed. The appendix vermiformis was found filled with a row of dense fecal concretions, tied off and removed. I herewith present the specimen, which will enable you to judge of the small size of the abscess.

As I have already stated, if the exploratory puncture had failed, which it luckily did not, to discover pus, I should have declined to operate, and thus have failed to restore to health and happiness a patient, when, as the result proved, it lay in my power so to do. I have, however, never as yet removed the ovaries or tubes, except for gross palpable lesions of these organs or in cases of uterine myoma. I have not, as yet, met the case in which I considered the removal of normal ovaries for the relief of nervous symptoms indicated or justifiable.

Hæmatosalpinx.—Leaving now the subject of suppurative disease of the appendages, I desire to call attention to some cases, not, however, verified by operation, in which a diagnosis of hæmatosalpinx was made by the aid of exploratory puncture, as well as to one case where a hæmatosalpinx was found at operation, although I had failed by exploratory puncture to diagnosticate its presence. This subject of the differential diagnosis between hæmato- hydro- and pyo-salpinx is of peculiar interest, as, except by the aid of exploratory puncture I know of no way in which it can with any degree of certainty be made. In fact, the diagnosis of hæmatosalpinx is considered impracticable by most gynecologists.

CASE VIII. *Hæmatosalpinx (Tubal Pregnancy?) of Right Side.*—C. A——, aged twenty-two, married, no children, one miscarriage in May, 1889, came under my care January 14, 1890. Her previous history is unimportant. Has always been perfectly regular in her periods, flowing four days every four weeks, until November 8, 1889, when she menstruated regularly for the last time. Her periods did not appear when due in December, but two weeks later, December 22d, a flow came on which lasted until I first saw her. During the first week of this three weeks' flow there was considerable vomiting. During the entire period of three weeks, pain in abdomen, from umbilicus down, very severe at times and radiating down both thighs, was the chief and almost constant symptom. The pains were of a pressing and bearing-down character. The patient is unaware of the passage of anything but fluid blood from the vagina.

Uterus normal in size; cervix soft and slightly patulous; fundus deflected slightly to left. To right of uterus, high up in pelvis, an oblong, distinctly outlined tumor, three by two inches, with its long axis parallel to Poupart's ligament, can be readily made out. Left appendages normal. Right ovary, of normal size, can be felt in Douglas' sac. Right tube the seat of the swelling. Exploratory puncture of the latter yields a syringeful of bloody serum. Hæmatosalpinx, or pregnancy of the right tube, probably the latter, diagnosticated.

No particular treatment was urged for the present, as the removal of the serum from the gestation sac was considered sufficient to insure destruction of the fœtus, if the case were one of tubal pregnancy. If a case of hæmatosalpinx simply, laparotomy was not indicated.

Patient improved rapidly, went to Europe a month later, and at last report, September, 1890, had experienced no further symptoms. It will perhaps be conceded that the indications for laparotomy in the above case would have been considered sufficient by nearly all gynecologists, and imperative by many, and that the result of the exploratory puncture was the only thing that saved the patient from what proved to be an unnecessary operation.

I have on two other occasions, during the past eighteen months, made the diagnosis of hæmatosalpinx, based upon the finding, on bimanual examination, of an enlarged tube on one side, both ovaries and the other tube being normal, and the determination by exploratory puncture that the enlarged tube contained bloody serum. Unlike Case VII., however, there was in these cases no history pointing to a probable extra-uterine gestation. As the symptoms in neither case were urgent, non-interference and waiting were advised. Unfortunately neither of these patients returned after the first visit, and I was unable to ascertain what became of them.

In the following case a misinterpretation of the results of exploratory puncture led to a mistake in diagnosis, and to an unnecessary laparotomy, or, at least, to one which I should not have performed had I interpreted the findings correctly.

CASE IX. *Left Hæmatosalpinx.*—G. S——, aged twenty, single, was well up to May 22, 1890. On that day she took a bath while unwell. The flow lasted three days longer than usual, and she experienced abdominal pains, which, together with pain on micturition, have persisted to date.

June 11, 1890. Uterus normal in size and position, but impeded in its movements by a slight exudation all around. On the left an enlarged tube can be felt prolapsed into Douglas' sac. Exploratory puncture over the

top of fundus uteri, into the swelling occupying the posterior cul de-sac, gave negative results. A second puncture, more to the right, brought two or three drops of bloody serum. This was supposed, erroneously as it proved afterward, to have been derived from the peritoneal cavity.

Laparotomy, June 24, 1890. Recent serous peritonitis, with slight adhesions of pelvic viscera to each other and to intestines. A half pint of yellowish serum in the peritoneal cavity. Lying behind the uterus, in Douglas' sac, was a hæmatosalpinx of outer part of left tube two and one half inches long by one and one-half inch wide. Both ovaries and the right tube normal. The hæmatosalpinx ruptured on manipulation and discharged its contents, bloody serum, identical with that obtained on exploratory puncture. After rupture and evacuation of its contents the tube collapsed to about its normal size; the lips of the tear became nicely approximated. The abdomen was closed without removing anything except the yellowish peritonitic serum. The patient made an uninterrupted recovery and remained well.

Extra-uterine Pregnancy.—In the following recent case a diagnosis of tubal pregnancy, with rupture, was quite positively made at the first examination, and very materially by the aid of exploratory puncture.

Case X. *Tubal Pregnancy of Right Side; Rupture; Tubal Abortion; Intraperitoneal Hemorrhage.*—On October 11, 1890, I was asked by Dr. George F. Carey to see, with him, at her home, Mrs. M. Y——, married, twenty-six years of age. In March, 1885, she gave birth to her only child. Has always been perfectly regular in her periods, flowing seven days every four weeks, until August 8, 1890, on which day her last regular period began. Her next period was due September 5th She lost no blood, however, until September 10th, from which date until the present she has flown constantly. Crampy pains referred to the pit of the stomach and both iliac regions, and vomiting, at first in the morning, later on at all times of the day, were the other symptoms. Dr. Carey had discovered a swelling to the right of, and posterior to, the uterus, semi-elastic in consistency, and painful on pressure, which he strongly suspected to be due to an extra-uterine gestation. I verified the conditions above described. The uterus, of normal size, was crowded forward and to the left by the tumor situated to its right and posteriorly. I coincided with the diagnosis of tubal pregnancy of the right side, and with the kind consent of Dr. Carey, made an attempt to obtain further information by exploratory puncture. The needle entered the mass, and aspiration proved negative. While slowly withdrawing the needle, however, the vacuum in the barrel being maintained, and just as the point of the needle left the mass and became free in the peritoneal cavity, the syringe filled with thin, dark blood. An intraperitoneal hemorrhage, due to ruptured tubal pregnancy, was diagnosed. No symptoms of active hemorrhage being present at the time, the patient was transferred to hospital for operation.

Laparotomy, October 13th. Peritoneum contained about a pint of dark fluid blood, of the same character as that withdrawn by exploratory puncture, together with a handful or two of clots. Tumor, formed of a large firm clot, and of enlarged and ruptured right tube, occupied right side of uterus and Douglas' sac. The clot, a cast of the distended right tube, occupied the rent in the tube, and was situated partly in the tube, and partly in the free peritoneal cavity. Outer half of the tube enlarged, dilated, and hypertrophied. Inner circumference of enlarged portion varied between one and three-quarters and two inches; the rupture, about one and one quarter inch long, occupies anterior aspect of junction of middle and outer thirds of tube. Right ovary normal, but undersized. Clot removed. Ruptured tube and right ovary tied off and removed. Blood and clots removed from peritoneal cavity; free flushing of latter. Fœtus not found. Patient recovered without an unpleasant symptom. A microscopical examination of the tube and the clot contained in it, both of which I herewith present, failed to discover chorionic villi. The fœtus had either become absorbed in the peritoneal cavity, or had been washed out with the free fluid blood and clots.

I may be pardoned a few therapeutic considerations, upon which exploratory puncture has a bearing, in connection with this case. When the patient was first seen a tubal pregnancy of the eighth or ninth week, and, by exploratory puncture, the presence of free blood in the peritoneal cavity, were diagnosticated. There were at the time no indications of active hemorrhage going on. At the operation a pint of fluid blood and a handful or two of clots were found in the peritoneal cavity. The tube had ruptured and expelled the entire ovum into the peritoneum; in other words, tubal abortion had been completed, and the fœtus had perished in the abdominal cavity. There was no hemorrhage going on, and the coagulum which had finally closed the blood-vessels of the tube was in the process of extrusion from the latter.

On careful review of the case after operation, I could see no reason why the patient should not have recovered without laparotomy. The original cause of the hemorrhage had ceased to be operative; the fluid blood and clots in the peritoneal cavity would, in all probability, have been absorbed, either directly or after forming a hæmatocele. The ruptured tube would have undergone involution, and a tubo-peritoneal fistula, at most, would have been left to tell the tale of ectopic gestation. Without laparotomy, and with or without electricity, the patient would have gotten well.

The soundness of the recent advice of Olshausen[1] receives confirmation from this case. In cases of extra-uterine pregnancy in the first three months he urges immediate laparotomy (I would venture to substitute electricity, or perhaps simple puncture and aspiration of the amniotic fluid as in Case VIII.) if the case be diagnosticated *before* rupture; *after* rupture laparotomy should be performed only when the symptoms are extreme, and when the surroundings and conditions are such as to guarantee the possibility of an aseptic operation.

Exploratory puncture enabled me, in the above case, to diagnosticate a free intraperitoneal hemorrhage, which, coexisting with the symptoms and signs of a tubal gestation, indicated plainly that rupture had taken place. This fact is of value when we consider that we have no other positive sign of the presence of blood free in the peritoneal cavity.

One or two other practical considerations arise in connection with the case. Was it necessary, when performing laparotomy, to extirpate the recently pregnant, ruptured, and now cleanly empty tube? Could it not, with perfect safety to the patient, have been left to take care of itself, with or without freshening and suture of the rent through which the fœtus escaped? I am inclined to answer the latter question in the affirmative. Should I meet again with an identical case, I shall empty the peritoneum of clots and blood, and after assuring myself, by the passage of a probe, of the perviousness of the uterine end of the tube, I shall freshen and sew together the margins of the rent in the tube, drop the latter, and close the abdominal cavity.

Hydrosalpinx or Small Cystoma.—In the following case exploratory puncture led me to diagnose the existence of hydrosalpinx, or of a small cystoma, and, knowing that these conditions sometimes disappear spontaneously, to decline operative interference for the time being. The symptoms were not too urgent, there seemed to be no danger in delay, and the patient could be watched.

Case XI.—E. W——, aged forty-seven, married, gave birth to eight children, the last in 1879, and miscarried with twins in 1880. Patient was well, and periods were regular, until May 15, 1890. On that day metrorrhagia, with passage of clots, and colicky pains came on, and lasted until she came under my care on June 14th. Fre-

[1] Deutsche Medizinische Monatsschrift, 1890, Nos. 8-10.

quent and painful micturition accompanied these symptoms. Has not indulged in sexual intercourse for three years past.

Uterus normal in size and position. To its left, and posteriorly, can be felt an elongated mass, half as large again as the uterus itself, irregular in outline, soft, though not fluctuating.

Exploratory puncture yields a syringeful of pale amber-colored fluid, which froths on pouring into a test-tube, and is decidedly albuminous.

Diagnosis doubtful between small cystoma and hydrosalpinx, the character of the fluid pointing to the former, the shape to the latter.

Small Parovarian Cystoma.—During my experience with exploratory puncture I have encountered two cases of small cystomata of the parovarium. In one the diagnosis of parovarian cystoma was reached as the combined result of careful bimanual examination and of exploratory puncture, and confirmed by abdominal section. This statement embraces all of importance and interest in the case, and I shall therefore not describe it in detail. In the second case the diagnosis was not made, and as it illustrates well a possible source of error, already alluded to in the practice of exploratory puncture, I venture to give the particulars.

CASE XII.—C. M——, aged thirty-six, married, and the mother of seven children, was admitted to St. Francis Hospital, November 7, 1889. She has been under treatment, local and general, for eight years. During the past four years has been a constant sufferer from all sorts of aches and pains, being thereby, although of robust frame, entirely incapacitated for work. Her chief pain has been in the left iliac region. Her last regular period ended October 17, 1889.

Examination, November 10, 1889. Uterus of normal size; cervix extensively lacerated in various directions. A tumor with distinct outlines, and goose egg in size and shape, can be palpated in left ovarian region. Exploratory puncture of tumor with negative results.

After several weeks of general and local treatment, without improvement, laparotomy was performed on December 3, 1889. Fat abdominal walls. Uterus slightly enlarged. Both tubes and right ovary perfectly normal. Left ovary, enlarged to twice its natural size, forms one mass with a small parovarian cyst of the broad ligament. Cyst punctured and fluid evacuated. Nothing removed. Abdomen closed. In performing exploratory puncture the needle had entered the solid half of the tumor, composed of the ovary, instead of the fluid half, the attached parovarian cystoma.

February 5, 1890. Examination shows patient to be pregnant about three and a half months, and consequently to have been pregnant six weeks at the time of operation. Pregnancy went on undisturbed.

The Appendages in Fibroma Uteri.—Quite recently exploratory puncture decided for me a question of practical therapeutics in a case of uterine fibroma, the choice lying between electricity and salpingo-oöphorectomy.

CASE XIII. *Uterine Fibroid impacted in Pelvis; Adeno-epithelioma of Tubes and Ovaries.*—E. S——, aged forty-five, single, suffering from uterine fibroma, was sent to me by her family physician with a written request to continue a course of electrical treatment initiated and carried on for several months past, but without effect, by the family physician. A preference for electro-puncture was expressed in the note.

The patient was anæmic and cachectic in appearance, and gave a history of severe suffering for eight months past; had no abnormal hemorrhages. Her last menstruation occurred July 6, 1890, and was trifling in amount; she supposed herself to have reached the menopause.

On examination, October 10, 1890, the cervix is found forward of its normal position and low in the vagina. Uterus two and a half inches deep, the sound running anteriorly. A fibroma, a little over three inches in diameter, occupies the posterior wall of cervix and of body of uterus, and is immovably impacted in the pelvis beneath the sacral promontory. Pelvic cavity pretty well filled by uterus and fibroma. Both ovaries can be distinctly felt in about their normal position; they feel slightly enlarged and hard. Between uterus and left ovary a soft, fusiform enlargement, about twice the size of left ovary, can be felt. Exploratory puncture into this mass yields bloody serum. Right tube slightly thickened. The appendages being diseased, as evidenced by both bimanual examination and exploratory puncture, electricity was held to be contra-indicated and laparotomy called for.

Laparotomy, October 14, 1890. A pint of ascitic fluid in the peritoneal cavity. Both ovaries and tubes the seat of neoplasmic changes of a papillomatous appearance. On the right side the growth had infiltrated the peritoneum and subperitoneal tissues of the posterior pelvic wall. In removing it from this region the right ureter was laid bare for over an inch of its length, and alarming hemorrhage ensued. Ovaries and tubes on both sides tied off and removed. Hemorrhage controlled by packing left half of pelvis with iodoform gauze, the fibroma forming an excellent surface for counter-pressure. The fibroma could not be raised out of pelvis and was left unmolested. In the folds of the left broad ligament were three or four small cysts, pigeon-egg in size and shape, and containing bloody serum. One of these had been punctured by the exploring needle. A careful microscopical examination of the growths, kindly made by Dr. Eugene Hodenpyl, showed them to be adeno-epitheliomata. Dr. Hodenpyl believes them to be good examples of malignant disease engrafted upon ordinary cyst-adenoma.

Tuberculosis of Tubes and Peritoneum.—I have practised exploratory puncture in two cases of tuberculosis of both tubes, associated with general tuberculosis of the peritoneum. In one of them exploratory puncture gave absolutely no information; in the other it furnished evidence of a circumstantial nature which proved in some degree contributory to a correct diagnosis.

CASE XIV.—R. S——, aged twenty, single, admitted to St. Francis Hospital, July 8, 1889. Father and three sisters living; mother and one brother died of consumption. Patient dates her illness from April, 1889. Pains in lower part of abdomen the chief complaint. No cough, and but little cachexia or emaciation.

Examination shows both tubes to be decidedly and irregularly enlarged, averaging about the thickness of little finger. Exploratory puncture of both tubes with negative results.

Laparotomy not entertained at first. While under observation the tubal tumors very rapidly increased in size until they were one and a half inch in diameter; there was corresponding increase in pains and irregular fever. Rapidly filling pyosalpinx diagnosticated (without a second exploration by puncture) and rupture feared. Operation now advised. Tuberculosis not suspected.

Laparotomy, July 24, 1890. Tuberculosis, far advanced, of entire peritoneum. Primary tuberculosis of both tubes. No ascites. Abdomen closed without removing anything but a small piece of peritoneum for microscopical examination. The latter demonstrated the presence of the bacillus tuberculosis.

CASE XV.—A. G——, aged thirty, married, mother of seven children, came under my care April 28, 1890. Family history indifferent. Formerly suffered from some uterine displacement for which she wore a pessary. Present illness dates from February, 1890. It began with stabbing pains in right groin, which soon became general all over the abdomen. These pains have kept her in bed for two months past. Appearance that of a person greatly run down in health; anæmic, emaciated, listless, and cachectic. Mild pyrexia.

Abdomen tumid, irregular in outline. Tympanitic resonance on percussion everywhere except low down in right flank. Uterus normal in size and position; mobility impaired. In region of right tube an elongated in-

duration, about two inches long, can be felt. Left tube enlarged to about half this size. Douglas' pouch boggy to feel. Two or three enlarged sacral glands are found in the hollow of sacrum behind rectum. Spleen considerably enlarged and very hard, can be distinctly felt reaching downward to two inches below the costal margin. At various parts of the abdomen a few small nodular masses can be felt behind the thin abdominal walls and moving with them. Exploratory puncture of tubes negative. Puncture into retro-uterine space on two occasions, May 5th and May 16th, gives yellowish serum. Although especially examined for their presence, no bacilli tuberculosis were found in this fluid. The exploratory puncture, however, revealed the presence of ascitic fluid in the peritoneum before it had accumulated in sufficient quantities to be detected by other signs. The discovery of this fluid, coupled with the general symptoms and the nodular indurations of the parietal peritoneum, led to the diagnosis of tuberculosis of the tubes and peritoneum. This diagnosis was confirmed by laparotomy May 24, 1890.

Small Cystic Degeneration of Tubes and Ovaries.—I have removed the ovaries and tubes once for extensive small cystic degeneration of these organs. In this case exploratory puncture had been performed with negative results and had failed to throw any additional light upon the case.

Malignant Disease.—Quite recently exploratory puncture aided me materially in reaching a diagnosis of malignant disease forming a tumor of small dimensions. The subject is of sufficient general interest, perhaps, to warrant my reporting the case somewhat in detail.

CASE XVI. *Carcinoma of Posterior Wall of Caput Coli. Involving the Appendix Vermiformis and Right Ovary.*—M. S——, aged forty-two, married, gave birth to her only child in 1872. Has not been quite well since November, 1889. Pains in the right groin and in back, and more or less looseness of the bowels have been the main symptoms. States that she has lost considerable flesh, although at present not noticeably emaciated or cachectic in appearance.

September 18, 1890.—Uterus at normal height in pelvis, two and a half inches deep, immovable; fundus turned slightly to right. A hard, oblong tumor, of an average diameter of perhaps three inches, runs from middle of right Poupart's ligament over fundus and anterior surface of corpus uteri to left iliac region. Its right end is fixed, its left end freely movable in the abdominal cavity. Fundus uteri embedded in and immobilized by this mass. Exploratory puncture at two different points fails to find fluid. The needle, however, in traversing the tumor, gives rise to an exceedingly well-marked creaking sensation, identical with the characteristic creaking produced on cutting through a carcinomatous tumor with the knife. In my entire experience with exploratory puncture, I had never met with anything approaching this sensation. It impressed me as so characteristic that I had no hesitation in pronouncing the tumor malignant, and from the history of the case, as probably connected with some portion of the intestinal tract.

Laparotomy, September 23, 1890, verified the diagnosis. A carcinomatous tumor about two by two and a half inches in size occupied the posterior wall of the caput coli. It involved the appendix vermiformis, the right ovary, and somewhat more than the outer half of the right Fallopian tube. The intestines and omentum were matted together over the mass and around the fundus uteri. The carcinoma had so far involved the neighboring tissues and organs that an attempt to remove it was considered unjustifiable, and the abdomen was closed.

The above are some of my experiences with pelvic exploratory puncture guided by combined vaginal and rectal touch, as I would venture to designate the method. In presenting them, I have only utilized such cases of which I possess full records, and in which either a subsequent laparotomy, or observation of the further progress of the case, furnished data for an estimate of the value of the method. The method has, a number of times in addition, materially aided me in reaching a diagnosis and conclusions in regard to a case satisfactory to my own mind. But as such patients either disappeared from observation, or the diagnosis was not confirmed or disproved by laparotomy, I have not deemed them proper cases for the purposes of this paper.

As to the practical value of the method, each one, after an analysis of the above-recorded observations, will be in a position to reach his own conclusions. I have endeavored to refrain from presenting the favorable aspects of the matter in too strong a light, and have preferred to record more fully, and dwell at greater length upon instances demonstrating the shortcomings and the failures, more or less complete, of the method. I have done this believing that here, as everywhere, more is to be learned from an analytical study of our failures than from a mere rehearsal of our successes.

This much I think I may, in all fairness, claim for the above-described method of pelvic exploratory puncture: It has yielded me information of a very practical character in a number of cases, without ever doing the least harm to any of my patients. Not one of us can afford to disregard any means which will help to throw additional light upon a case, and thus enable him to do better for the patient who has entrusted her health, and often her life, to his hands.

The one consideration, however, from which I derive greater satisfaction than from any other, is that exploratory puncture has, in some of my cases, taken the place of, and rendered unnecessary, an exploratory laparotomy. Laparotomies have become such a daily, common occurrence that there exists the danger of losing sight of the fact that a number of simple exploratory laparotomies have proved fatal. Abdominal section is always a serious matter, and I cannot help being amazed at the flippancy of him who can find in any intrapelvic enlargement, with ever so slight or even no symptoms, the indications for a laparotomy, be it exploratory or otherwise. If the further elaboration of this method, and its trial at the hands of others with larger opportunities, will result in sparing some of their patients, as it has some of mine, the ordeal and risks of exploratory laparotomy I shall feel that my main object in writing this paper has been accomplished.

It must be evident from a perusal of the above that pelvic exploratory puncture, as here delineated, aspires to the dignity of a somewhat exact and scientific procedure. It presupposes not a puncture at random into the pelvis, but an attempt to guide the needle into the exact part to be explored, nay, approximately into any desired portion even of such part. It must be evident also that it is not a procedure to be practised indiscriminately by every one. A *sine quâ non* of its safe and successful employment is the possession of a fair degree of skill and experience in bimanual palpation of the pelvic organs. Perfection in this regard we may never hope to attain. There will always be cases which will baffle the greatest diagnostic acumen. Still I would, as a last injunction, urge that the method be attempted only by those whose tactile sense is sufficiently educated by daily practice to enable them to apply it with the greatest probability of attaining good and of avoiding mischief. Finally, to even such, I would say, as a parting word: Perfect asepsis, immobility of the needle, and resistance of the temptation to bore about in the tissues are the guarantees of safety.

198 SECOND AVENUE.

"Would any shock, at this stage of my trouble, cause a relapse, doctor?" inquired the patient. "Yes, and a serious one." "Please then, doctor, to remember that important fact in making out your bill."

A NEW RAPID TUBERCLE BACILLUS STAIN.

By MORRIS MANGES, M.D.,

PHYSICIAN TO OUT-DOOR DEPARTMENT MOUNT SINAI HOSPITAL, NEW YORK.

THE necessity of making the staining of the tubercle bacillus so simple and rapid that the process can be carried out by anyone has led to many improvements in the original methods of staining this organism.[1] Undoubtedly the greatest advance was made with the Ziehl Neelsen carbol-fuchsin solution; with it we not alone lessened the duration of the process but, what was equally important, we obtained a stable reagent which could be kept unchanged for months, and thus did away with the rather clumsy anilin-water staining solutions. Another advance was marked by the introduction of Günther's acid methylen-blue solution, by which the non-tubercular organisms were decolorized and differentially stained. Recently the technique of these methods has been improved and much time saved by doing everything on the slide, the covers, glasses, and dishes being superfluous. We refer to the method of Friedländer as announced in the *Therapeutische Monatshefte*, August, 1890, page 423. His method is as follows: the sputum is selected as usual and is spread with a clean needle or pair of forceps on a thoroughly cleansed glass slide in a thin layer till it covers a space about as large as a nickel. While this preparation is drying in the air, a second slide is prepared in a similar manner. Then draw the first preparation through the flame three times as usual. Now add to the slide two to three drops of Ziehl's carbol-fuchsin solution.

Sat. alcoholic sol. of fuchsin	10.0
Acid. carbolic. cryst.	5.0
Aq. destill.	ad. 100.0

Hold the slide over a flame, specimen side up till steam begins to come off; pour off excess of stain, and draw slide through a dish of distilled water. After draining off excess of water, add a few drops of acid alcohol solution.

Acid. nitric. pur.	5.0
Alcohol eighty per cent.	ad. 100.0

Allow it to act about thirty seconds, *i.e.*, till specimen is decolorized; then wash in water again; now add a few drops of a saturated watery solution of methylen blue; put slide aside without warming till we have proceeded thus far with the second preparation. Now again wash slide with water, drain off excess of water with filter paper, and allow it to dry. When dry, put a drop of cedar oil directly over the stained specimen (a cover glass is unnecessary) and examine specimen directly with oil-immersion lens. In the absence of the latter, a dry lens with magnifying power of about four hundred to five hundred diameters will suffice. If the focal distance is very small, or if the observer is not very skilful, the use of a cover glass is advisable. The careful examination of two such preparations will usually be sufficient to judge the sputum.

To recapitulate, the steps of the process are as follows: 1. Preparing smear on slide. 2. (*α*) Drying in air; (*β*) drawing through flame three times. 3. Two to three drops of Ziehl's carbol-fuchsin solution added to slide, and heated till steam comes off. 4. (*α*) Washing in water; (*β*) decolorizing with acid alcohol; (*γ*) washing in water. 5. Differentiating with aqueous solution of methylen blue. 6. Washing in water, and drying; clearing up with cedar-oil.

We have used this method and have obtained very satisfactory results with it, fully as good as those obtained with any of the other procedures. It is rapid, clean, and there is a minimum of dirty dishes, etc. In all the old methods duplicate smears are made on cover glasses, while here we can obtain a much larger area of the sputum for examination by spreading each one separately. These advantages are sufficient to commend its use, although it offers no new principles of staining the organisms.

We may be pardoned if we speak of a few details. It is advisable, though not absolutely necessary, to allow the fuchsin to act longer than is proposed, since we thus lessen the risk of decolorizing too much with the acid. It is convenient, then, to use a large amount of the stain (say five to six drops) to allow for evaporation, and after heating to put it aside on a level surface, while in the meanwhile we take up the second slide and bring it to the same stage. In warming no more heat is to be applied than will just cause steam to arise; if overheated, the specimen will be ruined. Filtration of the reagents, especially such as have been kept for some time, is absolutely necessary, and at the same time affords a very convenient way of adding solution to the slide. While it is quicker to dip the whole slide in a dish of water to wash off any excess of stain, yet a neater way is to use a wash bottle with distilled water; this also saves changing the water in the dish later on.

The method may also be simplified by using the acid methylen-blue solution, and thus combining steps 4 and 5 into one. We may use the ordinary formula:

Methylen blue	2.5
Alcohol	20.0
Acid. sulphuric.	25.0
Aq. destillat.	ad 100.0

In using this solution, allow it to act thirty to sixty seconds, wash off at once, and dry as before.

941 MADISON AVENUE.

[1] The full literature on this subject will be found in Flügge's Mikroorganismen, p. 15 (2d edition), and Weichselbaum, in Centralblatt für Bacteriologie und Parasitenkunde, vol iii., 1888, pp. 496-750.

Progress of Medical Science.

The Permanent Tube in Cancer of the Œsophagus.—Cases are reported by Dr. Gangolphe, in which the sound remained in the œsophagus for four, five, and even six months. Food was thus easily administered to patients, whose lives were thus prolonged and rendered more comfortable. In the following case the patient carried both a tracheal and an œsophageal tube at the same time. A woman, aged forty-five; tube No. 5 passed into the œsophagus on December 19th; cachectic and emaciated. She was unable to swallow solids. Liquids regurgitated with mucus. Unsuccessful attempts to pass bougies and tubes, as violent muscular spasm was induced, even by a finger in the pharynx. Under an anæsthetic, a stricture was made out at the junction of the pharynx and œsophagus, and by patience and care a No. 5 tube was passed into the stomach. Feeding was now easy, and soon No. 8 was passed, then No. 12. On January 12th, No. 16 was passed, then No. 20; but these sizes were found to be too large to be supported, and No. 8 was returned to. The patient improved in health. On March 2d, dyspnœa occurred with suffocative attacks, and it was supposed that the recurrent nerve was involved by the tumor. Tracheotomy was performed, and the patient now carried two tubes, a tracheal and an œsophageal. All went smoothly for some time, but on May 19th, seventy three days after the tracheotomy, she died suddenly in the middle of the night, owing to the falling in of the tube into the trachea. But for this accident she would have lived much longer. The autopsy revealed a tumor at the upper end of the œsophagus, involving both recurrent nerves. It was not ulcerated; the neighboring parts were not inflamed. Tubage has given better results than gastrostomy, even in the severest cases when liquids could not be swallowed. The indications for permanent intubation are variable. It has been called a blind procedure, anti-surgical, dangerous. This cannot be said of intubation in recent cases of cancer of the œsophagus, when liquids are still swallowed easily, still less when the course is rapid, and there is much spasm. Not only

must the caprices of the œsophagus be borne in mind, but also the hand of the operator. Patience, perserverance, and gentleness are absolutely necessary to triumph over all the obstacles. Even in old cases, with feeble subjects, and when there is complete dysphagia catheterization should be tried. In many such cases the stricture is found post-mortem to admit the passage of a larger tube than was expected. The great point to insist on is the use of intubation at an early date, before emaciation, dysphagia, and extreme cachexia have set in, and when the operation is easy and inoffensive, and the sound is well tolerated. The patient will always prefer this to catheterization. Sometimes the catheterization has to be intermittent, according as it is tolerated. If the trachea and bronchi are involved, as shown by the attacks of coughing, and the sanious and fetid expectoration, there will be risk of passing the sound down the trachea.—*The London Medical Recorder.*

Vomiting of Obscure Origin in Children.—Dr. Joseph Stedman read a paper before the Obstetrical Society of Boston, calling attention to cases of persistent vomiting occasionally met with in young children, where the etiology is obscure, and where the resultant exhaustion may become a source of much anxiety to the physician. He reports several cases which resemble each other in their general features. There is no gastritis, no fever, but the pulse may be somewhat elevated. The vomiting is severe and most persistent, and is usually sudden in its inception; the bowels may be constipated. Medical treatment seems to be of little avail, and the vital forces are rapidly reduced. The writer knows of no explanation for this save that offered by Dr. Rotch, who was called in consultation in one of his cases. The cause for the vomiting appears to be outside of the stomach, rather than from some direct lesion in the stomach. This leads to the impression that the vomiting is cerebral, and for this reason an unfavorable prognosis is sometimes given, though the face of the child is not that of cerebral disease, but of distress from nausea. Rotch believes the seat of the irritation will be found to exist in the great abdominal ganglia of the sympathetic system. Certain individuals seem to have an idiosyncrasy for being affected in this way. The causes which precipitate the attacks seem to be sudden changes of temperature, fright, shock from a blow on the epigastrium, and excitement, either direct or from anticipation. The disease occurs in infants as well as children; the breast-fed as well as the artificially fed, and in children whose diet has been most carefully supervised. The first indication for treatment is, of course, absolute rest; the room should be quiet and sunny, and the patient subjected to as little disturbance as possible. No food should be given by the stomach, occasional nutritive enemas of peptonized milk or Valentine's meat juice being given instead. Small doses of chloral and bromide of potash may be given by the rectum to procure sleep and stimulate the nervous centres. The recovery is often as sudden as the onset of the disease, but relapses occasionally take place. When the child commences to take food by the mouth, it is well to proceed cautiously and systematically, not only quantity but quality being considered. The nervous system must be carefully watched, and all excitement forbidden until the patient is well and strong, or in its normal condition once more.—*Annals of Gynæcology and Pædiatry.*

Cannabis Indica in Gastric Disorders.—After a full discussion of the forms of indigestion that are recognized, and the use of cannabis indica in their treatment, Dr. Sée arrives at the following conclusions: 1. The most convenient form in which to employ the drug is the extract in doses of about three-quarters of a grain daily, divided into three portions. Above this dose the drug is apt to produce unpleasant effects (The French extract is stronger than the English.) 2. The drug was chiefly tried on the non-organic affections of the stomach. These were divided into two groups. The first included cases in which the gastric juice was altered in composition, especially if there was an excess of hydrochloric acid. The second group consisted only of cases of gastro-intestinal neuroses, in which there was no change in the digestive juices. 3. All these affections—dyspepsias and neuroses—were characterized by five sets of symptoms, occurring in various proportions. (*a*) Pain, local or radiating, arising spontaneously or after food. The variations in appetite belong to this group. (*b*) Atony of the stomach, with or without dilatation, is almost always present. Vomiting is more frequent in the neurotic cases. (*c*) Flatulence and eructation occur in most cases; in the neuroses the gas consists chiefly of air which has been swallowed; gases formed by decomposition arise from lactic or acetic acid fermentation, and not from excess of hydrochloric acid. These gases are the cause of the painful symptom known as "heartburn." (*d*) The gastric digestion of flesh food and albuminoids is little affected when hydrochloric acid only is in excess, but it is deficient when too much lactic or acetic acid is present, and completely in abeyance when there is deficiency of acid. In the neurotic cases gastric digestion is normal. Constipation is the rule in most cases. (*e*) In this last group are placed the varied symptoms—giddiness, migraine, palpitation, agoraphobia, etc. 4. Cannabis indica gives relief from pain and increases the appetite in all cases, no matter on what causes the pain and loss of appetite may depend. If, however, too much hydrochloric acid be excreted, it is better to aid the action of the drug by large doses of bicarbonate of soda, given about four hours after food. Cannabis indica has no beneficial action on the atonic state of the stomach, but it relieves vomiting and cramp of the stomach. The drug has no direct influence in checking flatulence, but it aids the expulsion of the gas and diminishes heartburn. The digestion of food is improved, if the failure depends upon neuro-paralytic conditions, or is rendered painful by an excess of acid, but no improvement is produced if the disorder is caused by a want of acid. As regards the other symptoms—giddiness, sleeplessness, palpitation, and the like—some relief is generally experienced by the use of this drug, but no alteration for the better is noticed in the hypochondriacal, hysterical, or neurasthenic conditions. In short, cannabis indica may be said to be a true sedative to the stomach, without causing any of the inconveniences experienced after the administration of opium, chloral, or the bromides. It should be combined with the use of alkalies in large doses and with mild aperients.—*The Lancet.*

Amputation for Diarrhœa.—Velpeau had once in his service a poor devil attacked with a suppurating white swelling of the knee-joint, which had caused the patient to have an uncontrollable diarrhœa. The limb was useless, and ampatation was performed on the axiom "*sublata causa*," etc. The intestine recovered its good health and reposed from its past fatigues. Some days after the operation the eminent surgeon, showing the patient to the pupils following, said, with his characteristic bantering humor: "See, gentlemen, how the amputation of a leg can cure chronic diarrhœa!" A strange physician present made careful notes of all the great surgeon's remarks, and at the close of the hospital visit approached Velpeau and spoke as follows: "Sir, in the place I come from I have a patient whose diarrhœa has lasted for fifteen months, and cannot be checked. I have employed all known remedies and failed. To relieve him of his malady I shall cut off one of his legs as soon as I return home."—*Lancet Clinic.*

The Best Way to Cover the somewhat strong and disagreeable odor of naphthalin is to sublime it together with a little gum benzoin or benzoic acid. The desired effect is produced by simply mixing the two substances together.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place

New York, November 22, 1890.

THE PULMONARY CIRCULATION AND THE TREATMENT OF HÆMOPTYSIS.

IN the Harveian Oration for the present year, delivered by Dr. James Andrew, some facts of extreme interest are brought to the attention of the practitioners of medicine. Dr. Andrew takes for his subject the relations of physiology to medicine, and as illustrative of this relation he gives us some results of his investigations upon the pulmonary circulation.

He begins with a statement of the present unsatisfactory condition of our knowledge and therapeutic resources in regard to hæmoptysis.

This is a list of the remedies for this trouble given in a standard text-book on therapeutics:

"Acetic acid, aconite, alum, ammonium chloride, arnica, astringent inhalations, barium chloride, chlorodyne, chloroform to outside of chest, copaiba, copper sulphate, digitalis, dry cups to chest, ergot and ergotinin, ferric acetate, ferri persulphas, gallic acid, hamamelis, hot-water bag to spine, ice, ipecacuanha, iron and absolute rest, lead acetate, matico, morphine, opium, phosphoric acid, potassium bromide, potassium chlorate, potassium nitrate, pyrogallic acid, silver oxide, sodium chloride in drachm doses, subsulphate of iron, sulphuric acid, tannin, tr. laricis, turpentine, veratrum viride."

"Now, on looking through a long list like this," says Dr. Andrew, "one's first and last thought is that it gives us a very good illustration of the truth of the old axiom that, when many drugs are supposed each to cure one and the same disease, we may safely hold that few, if any of them, have the least influence over it."

There is no positive proof that a single drug on the list does any good whatever. Furthermore, many of the remedies are based upon entirely erroneous chemical or physiological views.

The pulmonic and systemic circulations are in reality independent to a great extent. We cannot judge of the pulmonary circulation by the pulse at the wrist, as is often attempted. The pulmonary pressure is in lower animals from one-third to one-fifth lower than the systemic. It is under vaso-motor control to a less degree, and this vaso-motor control is not affected in the same way or by the same agencies as that of the systemic vessels.

Dr. Andrew reports the results of a series of experiments for the purpose of determining the simultaneous action of certain drugs upon the pulmonary and systemic pressure. These are so striking that we quote several of them in full.

Muscarin in a small dose causes rapid fall in carotid pressure, and a striking rise in pulmonary pressure (in rabbits.)

Nitro glycerine.—In the cat $\frac{1}{50}$ gr. produced a temporary great fall of the carotid, with a slight rise of the pulmonary pressure. When, however, the carotid fall had reached its lowest point the pulmonary pressure also fell. The carotid pressure then rose, but not to the normal figure. At the beginning of this rise the pulmonary pressure showed some tendency to fall, but remained nearly constant. In the dog $\frac{1}{50}$ gr. produced a primary fall in the carotid, with little or no effect on the pulmonary pressure. A subsequent gradual rise of the carotid pressure then took place, with a very slight fall of pulmonary pressure during the greater part of the rise.

Digitalis.—Digitalin caused steady rise of blood pressure both in carotid and pulmonary arteries, with great slowing of pulse. Tinct. digitalis: In dogs, slight fall in carotid pressure following soon after injection. At this time practically no effect on pulmonary pressure. Following this a steady rise in both pulmonary and carotid blood pressure. Inf. digitalis: In cats, primary rise in blood pressure both in carotid and pulmonary arteries, followed by slight but more permanent rise. (The primary rise here was probably due to the fact that a large quantity of fluid had to be introduced, as the same result followed the injection of a similar quantity of water.)

Tinct. Strophanthi.—In cats, a small dose (namely, ♏ j.-ij.) produced a primary fall of pressure in both carotid and pulmonary arteries, and a subsequent rise in pressure almost up to normal; heart at same time slow and irregular. A large dose produced first a great rise of carotid pressure, the pulmonary pressure sinking at first and then rising slightly. Then great quickening of heart with steady fall of pressure in carotid; the pulmonary falling to, but not below, its original level.

Ergot produces primary rise in pulmonary, with simultaneous fall in carotid pressure. This rise, however, is of short duration. Subsequently both pressures rise.

Aconite produces fall in pressure in both carotid and pulmonary arteries.

Strychnine, in both carotid and pulmonary arteries produced a rise in pressure, especially marked in the pulmonary.

Chloroform.—Both pressures fall together.

Ether.—Both pressures rise together.

Atropine (*Sulphate*) produces first a steady fall in carotid pressure, the pulmonary sinking at the same time but in much less degree. During this period the heart is slowed and the vagus nerve is excitable. Next pressure rises in both, and pulse becomes more frequent, the inhibitory power of the vagus being gradually abolished. When the pressure reaches its highest point, the heart cannot be stopped by stimulation of the vagus, and a second dose of atropine will have no further effect.

The conclusions drawn from these experiments are not very definite; but they show that a drug which increases or lowers systemic pressure may have no effect on the pulmonary pressure. They show that if the systemic pressure rises, then the pulmonary pressure also rises; if the systemic pressure falls, then the pulmonary

may either rise or fall. But this is only true of the primary effect of the drug, for among the later effects, for example, in the case of amyl nitrite, and to a less extent in that of nitro-glycerine, the pressure in the pulmonary artery may fall while that in the carotid is rising.

It is suggested, finally, that aconite rather than ergot would have the most effect in pulmonary hæmoptysis.

Dr. Andrew has certainly opened up a very interesting field for further research.

THE ETHER HABIT.

THE descriptions given by Mr. Ernest Hart regarding the practice of ether-drinking in Ireland have excited a great deal of attention. The habit, in certain parts of the country, seems to be very prevalent and very harmful in its effects. In two small villages, for example, two tradesmen are known to sell over five hundred gallons annually. It is sold by manufacturers at the rate of about seventeen cents a pound, or about a cent an ounce, and its retail price makes it the cheapest of intoxicating liquors.

The stuff is bought of grocers and druggists, and is drunk in doses of two to four drachms, though experienced drinkers by holding the nose can take more. It is generally drank pure, though some add water or take a preliminary mouthful of excipient.

A single draught produces intoxication in one not used to it; but regular drinkers can take six or seven.

The immediate effects of drinking ether, says Mr. Hart, are similar to those produced by alcohol, but everything takes place more rapidly; the stages of excitement, mental confusion, loss of muscular control, and loss of consciousness follow each other so quickly that they cannot be clearly separated from each other. It is only the "immoderate" ether drinkers who drink themselves into stupor; many are content not to go beyond the stage of exhilaration, when they become very talkative and laugh hysterically. The effect wears off almost as speedily as it comes on.

With regard to the more remote effects of ether, there is not much to be said. Very little appears to be known by pathologists of any injurious effect it may have on the tissues. There are no gross lesions like the shrinking and induration of brain and liver characteristic of alcohol; ether is a thief that steals away the brains without leaving any visible mark of his presence. Mr. Hart made special inquiries as to its effect on the health, and, so far as "moderate" drinkers are concerned, there did not seem to be any evidence that the habit produces anything more than chronic gastritis and dyspepsia. With regard to the worst cases, however, a careful observer writes: "In ether drinkers who have long followed the habit I have seen general debility, great nervous prostration accompanied by tremors (muscles of neck and forearm mainly affected), indigestion, irregular action of heart, subacute gastritis, a peculiar white, sallow complexion, and in some cases (personally observed) a peculiar livid, cyanotic face."

Dr. Walter Bernard notes the following among the injurious effects on health which ether-drinking gives rise to: "Absence of subcutaneous fat, muscular wasting, feeble circulation, pale lemon and brown colored skin, reflexes exaggerated, especially knee-jerks." One terrible effect of ether-drinking is the profound degeneration of the moral character, which it often induces.

Ether-drinking prevails to a certain extent in this country, but it probably never will be popular as long as American whiskey is cheap.

"THE KOCH CURE FOR TUBERCULOSIS."

THE news during the past week regarding Koch's cure for tuberculosis has in the main confirmed our predictions as to its nature. It is not strictly a germicidal lymph, but practically it amounts to the same thing, for its curative powers depend upon its specific action upon the bacillus and its products.

Hence we can only repeat what Koch himself admits, that it can cure the first stages of phthisis only, and can have no great effect alone upon the secondary and suppurative processes.

It is somewhat curious also that so much stress is laid upon its curing lupus. Now lupus is considered a cutaneous tuberculosis, and the tubercle bacilli are found in the diseased tissue. Yet it has not been demonstrated to be a tuberculosis of the skin in any such direct and positive manner as phthisis has been shown to be a pulmonary tuberculosis; and there still is doubt as to the true pathogeny of the affection. The announcement of relapses of the lupus cases is not surprising. Dr. Koch proposes that his curative lymph be called "parataloid." It is of not much use to speculate as to its composition, since this we shall probably soon know. It is apparently of the nature of a ptomaine or product of bacillary life. The cyanide of gold, which it is said to contain, may be presumed to be added more to preserve the lymph than for its specific effect. At any rate, cyanide of gold has been given therapeutically heretofore, and has never shown itself of any especial value.

The action of the "parataloid" seems at first sight most extraordinary. It picks out the tubercular tissue, viz., giant-cells, lymphoid and epithelioid cells, and kills them; the destroyed products are then absorbed and carried away. This selective power of the remedy is the more strange, for the reason that there is nothing specific in these particular elements; they are all found in normal tissues, and it is only their proportions to each other and peculiar anatomical relations which are, so to speak, pathognomonic.

However, the same thing may be said of syphilitic products, yet these are picked out, destroyed, and absorbed by the action of mercury and iodide of potassium.

One must not judge too quickly as to the wide possibilities of future therapeutic measures discovered along the same lines as those followed by Koch. "Parataloid," if it does destroy tubercle, destroys one of a group of infective granulomata. The others of this group are syphilis, glanders, farcy, leprosy, actinomycosis, and rhinoscleroma. These may be attacked by similar measures, perhaps; but the cancers belong to another pathological group and may require entirely different methods.

Still the imagination cannot fail to be impressed by the possibilities in therapeutics apparently opened up by Koch. If his discovery turns out to be all that he hopes, the impulse to further research will be immense. The death-blow will have been given forever to therapeutic nihilism.

Medicine can hold up its head as a science, and defy with confidence all the jeers that may be thrown at its inefficacy. Every physician will feel prouder of his calling, more certain of its utility, and more earnest in its pursuit. We hope that all which Koch promises will be fulfilled; it would be a profound catastrophe to medical science if his "parataloid" should now fail.

"THE PHYSICAL CAUSE OF THE DEATH OF CHRIST."

WHILE desiring to exercise every courtesy to our contributors, it is rarely necessary to apologize for them and for ourselves for anything that appears in our columns. We regret to say, however, that we are compelled to do this in reference to an article by Dr. C. C. P. Clark, of Oswego, which appeared in our issue of last week. Although we do not consider ourselves responsible for the views of any author, we do not aim to be the medium of publication of other than strictly scientific discussions. In reading the article more critically after than before its publication, we confess that its appearance in the RECORD was a mistake. With all due deference to Dr. Clark's right of opinion, it is proper for us to disavow any intention of fathering it, directly or indirectly, or of disturbing the religious convictions or shaking the Christian faith of any of our readers.

The discussion of what he would imply to be the essential points in his paper, would carry us beyond the scope of a strictly scientific journal, and involve the consideration of purely theological questions, with which we have nothing to do. It goes without the saying, that it would be out of place in this journal, even if it were necessary, to show from sacred and profane history, and by those canonical Scriptures whose authenticity and genuineness are accepted by believer and non-believer alike, that Dr. Clark's theory is absolutely untenable, and, even on strictly scientific grounds, unworthy of consideration. In accordance with such views we shall decline any further discussion of the subject in our columns.

DIRECT NEWS FROM KOCH'S LABORATORY.

THE great interest which has been manifested in the new method of treating tuberculosis, advocated by Professor Koch, of Berlin, has prompted us, on behalf of our readers, to take extraordinary means of placing before them the latest and most trustworthy data concerning it. For this purpose we have sent a special correspondent to Berlin, who will work in Professor Koch's laboratory and cable a weekly letter therefrom to the RECORD. The gentleman is Dr. Max Einhorn, of this city, who was a pupil of Professor Koch, and whose studies and researches in bacteriology, internal medicine, and organic chemistry peculiarly fit him for the special study he is to undertake. We shall thus have the latest information direct from the laboratory, and also from the various leading clinicians who are giving the method a trial. Until Dr. Einhorn's arrival in Berlin, which will be in the course of a few days, we have the means through our regular correspondent of supplying our readers with all the new and essential facts connected with the discovery which may be obtainable from that city.

News of the Week.

A New Bogus Medical College has been unearthed at Newbury, Vt., having the name of the Union Medical Institute.

Nearly Two Thousand Physicians are said to have gone to Berlin to study under Koch. Professor Bergmann delivered a lecture Monday at the Berlin Clinical Hospital, on thirty-nine cases treated by him according to the Koch method. The patients were suffering from various tubercular affections of the joints, bones, skin, glands, throat, and mouth. One of them was suffering from a tumor on the larynx, and it was doubtful whether the affection was a tubercular or a cancerous one. He was treated in the manner laid down by Professor Koch, and, as there was no constitutional reaction, Professor Bergmann was led to express the opinion that the tumor was of cancerous formation. Professor Bergmann illustrated the value of the Koch method as an aid in diagnosis. Professor Bergmann also demonstrated the Koch cure before Dr. von Gossler, Prussian Minister of Ecclesiastical Affairs, Instruction, and Medicinal Affairs, and many noted physicians, including Dr. Kerschensteiner, of Munich.

A New Clinical Phonograph.—Dr. J. Mount Bleyer, of New York City, has for the past two years carried on experimental researches in the use of the phonograph, for the recording of voices of singers, characteristic coughs of the different throat and lung affections, normal and abnormal respirations, etc. These records can all be preserved for future references. As aids in teaching, and object lessons in diagnosis, these illustrative phonograms are no doubt of scientific value. A repetition of these experiments were made with a new invention of Lieutenant G. Bettini, which formerly were done with the Edison phonograph and utterly failed to give the result necessary for practical use. The Bettini recorder and reproducer is so accurate in reproducing the quality, pitch, and intensity of a record, that it will become a very useful apparatus. Through these additional perfections in the micro-graphophone of Bettini, he was able to fulfil his wishes. His intention is within a few weeks to be able to give the profession a valuable machine for aiding clinical studies. Dr. Bleyer is preparing an exhaustive paper on the use of the micro-graphophone, which will appear in these columns. He claims the priority to this mode of investigation over that of Dr. Felix Semon, of London, who recently began to demonstrate its value.

Death from Cocaine.—A dentist at Lille has been tried for manslaughter for having applied cocaine to a lady's gum with a view to tooth extraction, with the result that the patient died. The Court held that it was not proved that the administration of cocaine was the cause of death. The defendant was, however, fined fifteen francs for the illegal practice of medicine, cocaine being an anæsthetic which should be administered only by a doctor.

The St. Louis College of Physicians and Surgeons has a chair of Dermatology, and examines in that branch for the degree, so says its Dean, in reply to Dr. Morrow's assertion that colleges do not have such a course as obligatory.

The Electric Light as an Analgesic.—Von Stein, of Moscow, says *La France Medical*, reports several cases of different painful affections which have been relieved as if by magic by the electric light. The apparatus which he uses consists of a small incandescent lamp about two inches long, with a reflector in the shape of a funnel, which is applied directly to the skin over the seat of pain. For the head and neck it is left in position for ten or fifteen seconds, but for other parts of the body it remains from one to five minutes, or until the patient complains of the heat. The author has obtained remarkable results in cases of intercostal neuralgia, rheumatic pains of the shoulder, lumbago, and severe pain in other parts of the body. The number of applications for permanent relief differs much, sometimes one being all that is necessary.

A Letter from Benjamin Franklin Concerning a Flexible Catheter.—The first meeting of the Section in Genito-urinary Surgery was held at the Academy of Medicine on October 13th, at 8.30 P.M. Among those present were Drs. Otis, Bangs, Sturgis, Alexander, Brewer, Morrow, Brown, Gerster, and Fuller. Dr. Sturgis was elected President, *pro tem.* Dr. Alexander stated the object of the meeting and read a letter from the Secretary of the Academy granting permission to form a Section in Genito-urinary Surgery. The following officers were unanimously elected: *President*, Dr. F. N. Otis; *Secretary*, Dr. Samuel Alexander. It was decided to hold meetings of the Section on the second Thursday in October, December, February, April, and June. Dr. Otis delivered the inaugural address, and afterward presented to the Academy, through the Section, the following letter by Benjamin Franklin, in which he describes the manufacture of an extempore flexible catheter:

To John Franklin.[1]

"PHILA. Dec 8, 1752.

"DEAR BROTHER, Reflecting yesterday on your desire to have a flexible Catheter, a thought struck into my mind, how one might properly be made. And lest you should not readily conceive it by any description of mine. I went immediately to the Silver Smiths and gave directions for making one (sitting by till it was finished) that it might be ready for this post. But now it is done I have some apprehension that it may be too large, to be easy; if so a Silver Smith can easily make it less by twisting it on a smaller wire, and putting a smaller pipe to the end, if the pipe be really necessary. This machine may either be covered with small fine gut first cleaned and soaked a night in a solution alum and salt in water, then rubbed dry which will preserve it longer from putrefaction: then wet again and drawn on and ty'd to the pipes at each end where little hollows are made for the thread to bind in and the surface greased:—Or perhaps it may be used without the gut, having only a little tallow rubbed over it, to smooth it and fill the joints. I think it is as flexible as would be expected in a thing of the kind and I imagine will readily comply with the turns of the passage, yet has stiffness enough to be protruded; if not, the enclosed wire may be used to stiffen the hinder part of the pipe while the fore part is pushed forward, and as it proceeds the wire may be gradually withdrawn. The tube is of such a nature, that when you have occasion to withdraw it, its diameter will lessen whereby it will move more easily. It is also a kind of screw and may be both withdrawn and introduced by turning. Experience is necessary for the right using of all new tools or instruments and that will perhaps suggest some improvements to this instrument as well as better direct the manner of using it.

"I have read Whytt on Lime Water. You desire my thoughts on what he says. But what can I say? He relates facts and experiments, and they must be allowed good, if not contradicted by other facts and experiments.

"May not one guess by holding lime water some time in one's mouth whether it is likely to injure the bladder?

"I know not what to advise, either as to the injection or the operation. I can only pray God to direct you for the best and to grant success.

"I am my dear brother
"Yours most Affectionately
"B. FRANKLIN.

"I found Whytts experiments are approved and recommended by Dr. Mead."

[1] Address "To Mr. John Franklin, Boston. Free: B. Franklin."

The meeting adjourned, to meet December 11th, at 8.30 P.M. The work of this Section will include questions relating to syphilis, and the venereal diseases, as well as to genito-urinary surgery.

Seventh International Congress of Hygiene and Dermography.—Dr. John S. Billings writes: "I am requested, by the honorable secretaries of the Committee of Organization of the Seventh International Congress of Hygiene and Dermography, to call attention to the fact that this congress will be held in London during the week beginning August 10, 1891. The governments of all countries and municipalities, and all public health authorities, universities, colleges, and societies occupied in the study of the sciences more or less immediately connected with hygiene are invited to coöperate and appoint delegates to represent them at the congress. The Prince of Wales will preside. A committee of organization has been formed, of which Sir Douglas Galton is chairman, and Professor W. H. Corfield and Mr. Shirley F. Murphy are honorary secretaries. An exhibition of articles of hygienic interest will be held in connection with the congress. The last of these congresses was held in Vienna in 1887, and was attended by over two thousand persons, and it is expected that the London meeting will be one of great magnitude and importance.

A New Hospital is to be built in Long Island City.

A Hospital Staff Resigns.—It is announced that a sensation in the medical as well as social circles of Ottowa, Canada, has been caused by the removal of Dr. Rogers, a prominent physician, from the staff of medical directors of the Protestant Hospital and the selection of Dr. Kidd to fill the vacancy. The members of the medical staff of the institution have resigned. A peculiar feature of the affair is that there is not the slightest reason advanced for the removal of Dr. Rogers. Although the staff have resigned, their resignation does not take effect till the next meeting of the directors. The visiting medical staff includes Sir James Grant.

Koch is now a "biger" man than old Bismarck.

Light from a Theosophist.—Again we asked, "Why are these clairvoyants and sensitives mostly women?" "Because," the theosophist answered, "women have a larger solar plexus than men. The solar plexus is, so to speak, the mind of the soul."—*The Nightingale.*

Is Tonsillitis Contagious?—In the *Medical and Surgical Reporter*, November 8th, Dr. Fred. T. Kidder reports a number of cases of follicular tonsillitis, apparently showing that the disease is contagious. In one instance the doctor himself suffered from a sharp attack of tonsillitis nine days after beginning the treatment of a case. Out of a family of seven six were taken down one after the other. In another family, mother and son were attacked, also a young lady who visited them while they were sick.

Dr. Richard J. Levis died at Kennett, Pa., on November 12th, of pneumonia. He was born in Philadelphia, in 1827, and was the son of Dr. M. M. Levis. He studied medicine at Jefferson College, in Kennett, and graduated in 1848. Dr. Levis was at various periods during his active professional life surgeon to the Wills Eye Hospital, to the Philadelphia Hospital, the Pennsylvania Hospital, the Jefferson Hospital, and the Philadelphia Polyclinic and College for Graduates. From 1877 to 1887 he occupied the position of President of the Board of Trustees of Jefferson College. He also served as President of the Medical Society of the State of Pennsylvania in 1885, and as President of the Philadelphia County Medical Society during 1885–86. Dr. Levis retired from practice in 1887.

Dr. H. M. Lyman has been appointed Professor of the Principles and Practice of Medicine in Rush Medical College.

Dr. Samuel A. Woodward, in a recent article in the *Journal of the Military Service Institution,* advocated an excellent plan for elevating the status of the medical profession in the army.

Vaccination on the Leg.—Some years ago, says the *Medical Standard*, a small panic broke out among actresses, and many of them not being able to pay conveniently the $5 usually charged by a practising physician for vaccination, applied to the health department. One and all had objection for practical, professional, as well as æsthetic reasons to having their arms marked up, and they were vaccinated on their legs. The calf of the leg was the part chosen for the insertion of the vaccine. The patients were in walking dress, and the proceedings disturbed the peace of mind of the young doctors who did the tattooing. One actress complained that she had not been vaccinated properly because the physician's hands trembled.

Death from an Overdose of Paraldehyde.—A patient in the Fever Hospital attached to the Cork Workhouse died from the effects of paraldehyde. The deceased, aged twenty, was admitted suffering from typhoid fever, and but slight hopes were entertained of her recovery. As she was suffering from violent delirium and sleeplessness, a hypnotic was prescribed. The patient getting worse, instead of giving one teaspoonful, the nurse unfortunately administered the entire contents of the bottle —viz., from six to seven teaspoonfuls. In about five minutes the patient fell into an unconscious state, and, despite medical assistance, remained in that state for four hours, when she died. The quantity of paraldehyde that was administered is not mentioned, but it may be supposed the deceased girl took from six to seven drachms.

Exploratory Laparotomy under Cocaine has recently been successfully performed by Dr. MacLaren, at the Cumberland Infirmary, England.

University Students in France.—In view of the measure which the Senate will shortly be called upon to discuss with regard to the creation of new universities in France, the Ministry of Public Instruction has prepared a very interesting return showing the number of students who at present attend the different French faculties. The total is 16,857, of whom 15,316 are Frenchmen and 1,471 foreigners, as against only 9,863 fifteen years ago. Out of this total, 5,843 students attend the faculties of medicine, 4,570 those of law, 1,834 those of literature, 1,590 those of pharmacy, 1,276 those of science, and 101 that of Protestant theology. Rather more than half of these (8,653) are students of the different Paris faculties; and, of the 1,271 foreign students, 1,078 are in Paris. With regard to the nationality of the foreign students, there are 989 Europeans (313 Russians, 159 Roumanians, and 121 Turks), 201 Americans (of whom 173 come from the United States), 68 Africans (of whom 51 are Egyptians), 12 Asiatics, and 1 Australian. The great majority of these foreigners are studying medicine, as 907 belong to these faculties, while 240 are studying law, 58 science, 39 pharmacy, 24 literature, and 3 Protestant theology.

Physicians off to Study the New Cure for Tuberculosis.—Drs. H. P. Loomis and J. H. Lindsley left this week for Berlin, in order to study the new method of cure. Dr Loomis we understand represents the University Medical School, Dr. Lindsley the Post-Graduate Medical School.

The Introduction of Morphia and Atropia before Anæsthetics.—Dr. J. C. Reeve, of Dayton, O., states: "Writing in haste to present my testimony in favor of this method, I find that I have been unjust both to myself and others. I learned the method of preceding anæsthesia with morphia from Bernard, but from publications earlier than his Leçons in 1875. His first publications on the subject were made in 1869. Moreover, Bernard did not use atropia in connection with the morphia. This was first distinctly taught to meet the dangers from chloroform by Bartholow, in his prize essay of the American Medical Association, 1869. My first publication of cases was in 1876, and I had then been using it "for six or eight years." Just when I first resorted to the two agents I cannot say, but I was very strongly impressed by Harley's teachings as to the stimulating effect of atropia on the heart and respiration, published in *Medical Times and Gazette*, 1868, and in "Old Vegetable Neurotics," 1869. Certainly I began to use it in 1869. That due credit should be given to Professor Bartholow is the more necessary now, since Dastre's work has just appeared (*Les Anesthésiques*, 1890), in which he claims this method for himself and M. Morat, and says they have resorted to is "for about ten years past!"

Society Reports.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, October 10, 1890.

GEORGE L. PEABODY, M.D., PRESIDENT, IN THE CHAIR.

Amyotrophic Lateral Sclerosis?—DR. BEVERLEY ROBINSON presented a patient with the following history: "William F——, aged twenty-three, single, native, telegraph operator for four years, bookkeeper for two years, admitted to St. Luke's September 19, 1890. His father died of consumption, mother of cancer, one brother died in an epileptic fit, one sister and three brothers are alive and well. Previous history: Scarlet fever when a boy, no sequelæ; no malarial, cardiac, pulmonary, renal, gonorrhœal, specific, nor alcoholic history.

Two years ago he had to give up telegraph operating, owing to inability to make the proper dashes. This difficulty had been coming on for about four months. He then commenced bookkeeping; was able to write, although with some difficulty, and continued at this until about a month ago. Then, owing to decline of general health and difficulty in writing, he gave it up. A year ago he first noticed stiffness in the right elbow, which has progressively increased. He also felt that the cords in front were getting more tense, and that the joint was getting larger. There was never any inflammation or pain in the joint. About six months ago his left wrist became swollen and painful; the pain went away in about five days, but the wrist was left swollen and stiff.

About a year ago he noticed that at the junction of the tarsus with the phalanges of the first three toes of the left foot there was pain, increased by walking; this has extended farther back on the sole of the foot, and has kept up ever since; there is also some stiffness of that foot.

Since about a year and a half ago he has noticed that the muscles of the hand, arm, and forearm have been becoming smaller; he has noticed some loss in the size of the leg also. In all he has lost about thirty pounds during this period. For about two years he thinks he has passed more water; he micturates more frequently, and has to exercise a good deal of will-power to hold the water when he desires to make it; he also has difficulty in expressing the water which remains in the urethra after emptying the bladder, and has to express it with the fingers.

He thinks he has lost memory considerably, and does not grasp the meaning of written things so well. He is able to walk perfectly well, and has yet a good deal of power in his hands and arms. His bowels are regular, appetite is very fair, he feels pretty well generally. His hands are always very cold. Temperature, 99.6° F.; pulse, 88; respiration, 24.

The result of the examination was as follows: Heart, apex in the fifth space, within the mamillary line, action regular, no murmur. Lungs negative. Liver, over its situation is tympanitic resonance. Spleen not made out. Abdomen negative; inguinal glands enlarged on both sides. There is atrophy of the muscles of the hand, forearm, arm, and shoulder, more marked on the right side. Very little, if any, atrophy of the feet and legs. Increase of wrist- and elbow jerk on both sides, especially the right; marked increase of knee-jerk; no ankle clonus; no plantar reflex; cremasteric and abdominal reflexes normal; sensation normal. Strength, as indicated by the dynamometer, right hand 60; left hand 68. Pulse, 72, regular, soft. Tongue moist, slightly coated with white fur. Papillæ, prominent. The urine contained no albumin, no sugar; specific gravity, 1.022; acid, with oxalate of lime crystals.

The notes of the examination by Dr. Robinson, October 4th, were as follows: Measurement of calf on left side, 11.25 inches; right, 11.75; thigh the same on both sides. Patella reflex, right markedly increased; left relatively diminished; wrist-jerk present on right, not on left. Elbow-jerk distinct on right, not very distinct on the left. Moderate pressure of the hand against the wrist on the left side causes pain. No apparent fluid in the joints. Decided thickening and roughening of the ends of the bones of the right elbow-joint with marked crepitus, faint on rotating the radius; bony limitation to motion in extending forearm. There is also enlargement of the bones of the phalangeal joint of second, third, and fourth fingers of left hand, right wrist, and fingers already mentioned. Right upper limb is decidedly smaller than left; dynamometer, right 65, left 72. No staggering on standing with eyes shut; walks naturally; eyesight normal.

Reaction of muscles of extremities to galvanism and faradism normal. There is relatively increased irritability of muscles of the right hand, arm, and forearm to both kinds of electricity.

DR. CURTIS examined the right elbow-joint and thought the condition might be tubercular. A foreign body recognized in the joint he thought pointed to its nervous origin.

In commenting upon the case, DR. ROBINSON said there was against the view that it was one purely of progressive muscular atrophy the fact that the reflexes were increased chiefly on the side most affected. There seemed to be a portion of the cord involved which presided over nutrition. There was no spasmodic condition, and no contraction of the muscles except in the right biceps, this being the only symptom pointing to an affection of the lateral columns of the cord. There was friction in certain of the joints, but no fluid. He had first thought of arthritic disease, more particularly in the right elbow, as the cause of the atrophy, and that this was dependent in some way upon his occupation. But there seemed to be no indication of it in the urine, in deposits of urate of soda about the joints, nor had he suffered especially from pain in the joints, thus excluding tabes dorsalis, rheumatism and gout, and other affections of the nervous system. He thought the case was probably one of amyotrophic sclerosis, although it was not typical of this disease.

DR. C. L. DANA said the case was a somewhat obscure one, and it was impossible to make a positive diagnosis on seeing it but once. It seemed to him, however, that it was not one of amyotrophic lateral sclerosis, an affection which was now generally regarded as essentially a progressive muscular atrophy with a slight variation in the usual clinical features. The Germans, in fact, regarded amyotrophic lateral sclerosis and progressive muscular atrophy as identical. Dr. Dana did not think it was a case of progressive muscular atrophy, for the reason that one arm was principally involved, and in the course of two years it had not extended much beyond that. Then, too, the finer muscles of the hand were very little involved. While there was another type in which the muscles of the shoulder and upper arm were involved, this case did not belong to that group. Here the muscles supplied by the ulnar nerve seemed chiefly affected. It struck him, therefore, that it was probably an arthritic affection.

DR. W. H. DRAPER said it did not impress him as a case of amyotrophic lateral sclerosis, or of any other central spinal disease, but rather as an arthritic affection with atrophic changes in the muscles. He had long been disposed to think that many arthritic lesions were of neural origin. If this supposition was correct, we still did not know whether it was a neuritis, an affection of the nerve trunks, or some central lesion. In the case under study he thought we should take into consideration the patient's heredity, his father having died of consumption, his mother of cancer, and one brother of epilepsy. It seemed, too, he had worked in unhealthy localities. Moreover, he had been engaged in telegraphy at the time the lesions began to appear, and the speaker had noticed that not infrequently rheumatic and gouty lesions manifested themselves

chiefly in parts most used. In laundresses, for example, the disease was apt to show itself in the upper extremities, while the lower extremities were most affected in those who walked a great deal. It had always seemed to him that the question of traumatism was an important one in the history of rheumatic lesions, those joints being most affected which were most exposed to strain.

DR. F. P. KINNICUTT said the case impressed him, both from the objective symptoms and from the history, as being one known as rheumatoid arthritis. The appearance of the joints, the partial ankylosis, the atrophic changes in the muscles, the way in which the joints had been attacked—first the elbow and the wrist, then the fingers of one hand, then the wrist and the fingers of the other; and although the patient had not complained of suffering much from pain, yet he said he had had very decided pain and swelling of the left wrist six months ago; then for the first time the trouble began in the small joints of that hand; and at present it would be observed that the small joints were affected in varying degree: all these facts, he thought, pointed to an arthritic trouble. Absence of pain was not very uncommon in rheumatoid arthritis—that was to say, of severe pain. The joints enlarged, became more or less useless, then there followed atrophic changes, finally contraction of the muscles. This, it seemed to him, was a very good example of that class of cases. He did not think there was a gouty, but rather a rheumatic element. But one saw cases of both gout and rheumatism almost imperceptibly passing into this condition. Not more than a year ago he had read an interesting article on this subject by a gentleman of Bath, England, who stated that he had seen a good many such cases; that persons came there to be treated for either rheumatism or gout, that these affections disappeared, but before the patients were scarcely aware of it there developed what he regarded as a different affection, a rheumatoid arthritis. This author had suggested that the part which gout and rheumatism took in the development of rheumatoid arthritis was to impair the nutrition by repeated attacks, leaving the tissues in a condition favorable for the development of a new and independent disease. Dr. Kinnicutt thought the feeling to day was that rheumatoid arthritis was probably of neurotic origin, and had no immediate connection with what we had hitherto considered either gout or rheumatism.

DR. V. P. GIBNEY doubted whether he could throw much light on the diagnosis, yet he thought he had felt in the right elbow bony crepitation, such as was observed in neuro-arthritic lesions. This crepitation had been observed in Charcot's cases, some of which the speaker had seen, and corresponded to an erosion of the cartilage. Until Dr. Draper had mentioned the fact, he was about to remark that it was difficult to understand why there should have been such extensive arthritic changes in the upper extremity when the lower extremities, especially the knees, had almost escaped. He now had a girl fourteen years of age under observation, every joint in whose body seemed implicated. The ankle joints were very much distorted. It could not have been due to occupation, for she had never worked. The patient presented showed marked freedom from crepitation in the distal joints of the fingers, yet, from his occupation, one might suppose they would be first affected. He was quite sure, he said, that this man had not arthritis deformans, meaning by that enlargement of the ends of the bones bordering on the joints. His seemed to be a case of true joint lesion. There was no bony enlargement, especially at the joints. He was disposed to regard the case as due to a cord lesion, the cord lesion being either the direct or predisposing cause.

THE PRESIDENT was rather impressed with the view that it was not a case of cord lesion, unless all cases of rheumatoid arthritis could be attributed to a cord lesion. There were several reasons why it should not be regarded as a case of amyotrophic lateral sclerosis—in that disease we did not expect an articular lesion, whereas involuntary spasmodic muscular contraction was marked. He was inclined to regard it as a case of rheumatoid arthritis; he thought that would account for the atrophic changes and for the condition of the joints

DR. ROBINSON would simply add that the electrical reactions and the tendon jerks pointed toward a lesion of the cord involving the lateral columns.

DR. DANA remarked that he did not think the elbow-jerk was much exaggerated. Besides, this man was of a nervous temperament; and probably his habits, use of tobacco, etc., had tended to exaggerate the reflexes.

Removal of the Drum-head and Ossicles for Chronic Catarrh of the Middle Ear.—DR. SAMUEL SEXTON presented a woman whom he had brought before the society at a meeting three years ago in illustration of a group of cases in which he had removed the drum-head and two larger ossicles for chronic catarrh of the middle ear resulting in deafness. At that time she could hear a loud voice only ten inches on the left side; to-day she could understand when spoken to in a voice a little above the conversational ten feet distant. The members were enabled to examine the ear under the electric light, and observed that the drum head had not been reproduced.

This was only one of many similar cases which he had operated upon, with much better results in some and not quite so good results in others. Altogether, however, the operation had proven very satisfactory. He was interested to learn while at the recent International Medical Congress that this operation was at present attracting a great deal of attention in Germany. Their results, perhaps, had at first not been quite so good as in America, for the reason, he thought, that they proceeded somewhat more actively to prevent regeneration of the drum-head. In Paris, Dr. Sexton found but comparatively little being done in the surgery of the ear, and in Great Britain the aurists were, perhaps, even more conservative than their French neighbors. The Germans were universally enthusiastic over the operation for the cure of chronic purulent otitis. In a number of cases this affection could not be cured in any other way than by removal of the dead structures.

Internal Medicine at the Berlin Congress.—This was the title of a paper read by Dr. Andrew H. Smith.

HARLEM MEDICAL ASSOCIATION.

Stated Meeting, November 5, 1890.

EDWARD FRIDENBERG, M.D., PRESIDENT, IN THE CHAIR.

Ectopic Gestation.—DR. F. H. DANIELS read an interesting and exhaustive paper on this subject. The paper, which will be published later, gave the full history of the causes, symptoms, and treatment of this interesting morbid condition, and reviewed extensively the literature bearing on it. The several propositions laid down were as follows: While it is possible under favorable circumstances to diagnose extra uterine pregnancy, there are no premonitory signs of rupture.

Rupture is inevitable in every case, and the rupture takes place in one of two directions. Either downward into the folds of the broad ligament, or upward into the peritoneal cavity. In the first instance the patient may recover by absorption of the ovum or by its development to term and thereafter. In the second instance death by hemorrhage will ensue if laparotomy is not promptly performed. The much-talked-of treatment by electricity ought to be abolished, as it is dangerous and inefficient. The cases of so-called extra-uterine pregnancy, reported by Drs. Thomas and others as cured by electricity, are to be doubted. They were probably some other tumor, and not extra uterine pregnancy. Laparotomy is the only justifiable means to be applied as soon as a diagnosis is made.

Discussion.—DR. MALCOLM MCLEAN: I agree fully with

the reader of the paper in his very accurate description of the causes, symptoms, and diagnoses of ectopic gestation. But I must emphatically differ with him in the management of these most important cases. Dr. Daniels takes his stand with other progressive surgeons in Europe like Dr. Tait. But I regret that any American surgeon should sweep aside the value of electricity in the condition under discussion. I believe a majority of cases of so-called extra-uterine pregnancy operated upon by Dr. Tait are no other than blood-clot in the Fallopian tube. The symptoms of extra-uterine pregnancy can be recognized; and electricity is a most efficient agent to cure the patient. I have positive evidences of this in several instances. If these tumors are found beside the uterus, with other signs of pregnancy, and become absorbed under the use of electricity properly applied, what can they be but the products of conception? I know of no cystic tumor which can be so absorbed. I saw a case, with the late Dr. D. C. Cocks, of extra-uterine pregnancy at the tenth week, four able physicians having agreed upon the diagnosis. Electricity was used, and the pain was immediately relieved and the tumor gradually diminished, until six months later a mere nodule remained. In medicine or surgery we are forced to make a diagnosis on a collection of rational and other symptoms. We are certain of nothing but what our eyes see. But, given pain and discharge of deciduous membrane, also a tumor different in character by its rapid growth, etc., from all other known growths, if now electricity be applied, and the mass disappear and the signs of pregnancy are removed, what rational inference can we draw?

Dr. Janvrin places on record a case where electricity failed to cure and the patient died; but he admits that hemorrhage had already taken place, and asserts electricity was not responsible for the death. Before the twelfth week electricity is almost certain to kill the fœtus. But as the patient lives we can't produce the specimen. I saw a case where the sac had ruptured and the limbs of the fœtus could be felt through the vaginal walls; an operation was urged, but refused. She made a spontaneous recovery, and I have subsequently confined her with placenta prævia. I am not certain that the tube always ruptures, and on this assertion I suppose I stand alone. I have here before the Association the fœtus, which I removed at the end of the twelfth month. The case was published in full in the *American Journal of Obstetrics and Diseases of Women and Children*, vol. xxiii., No. 4, 1890. The fœtus was living up to the ninth month, and every indication of labor came on, but no result. Some weeks later the case came under my care (at the twelfth month). I operated and cut through the placenta, which was easily removed. No hemorrhage took place. The sac was connected to the right horn of the uterus, and was none other than the distended Fallopian tube. It was left as found. The patient made a good recovery and is now six months pregnant (intra uterine).

A very important diagnostic point is this: If the amniotic fluid has begun to be absorbed and the tumor is, in consequence, growing less, then it is safe to assume that the placenta is dead, and no harm will result in its removal. In the same week that I operated, a surgeon in one of the Southern States cut through a live placenta and lost his patient on the table through hemorrhage. In that case there had been no absorption of the amniotic fluid.

Dr. A. D. Rockwell: For many years my attention has been called to another department of medicine, and I do not pretend to be an expert in obstetrical science. Still, I have had some experience in the use of electricity in ectopic gestation. Dr. Daniels is mistaken when he states in his paper that electricity was first used in 1872 for the cure of extra-uterine pregnancy. I believe electricity was first employed by myself for this condition in 1881. All told I have had fourteen cases, and the diagnosis was made by very eminent men, such as Emmet, Sims, Thomas, and others equally renowned. So there could be no doubt as to the diagnosis. I believe the use of electricity in this morbid condition to be most valuable. Specialists are not called now as frequently as a few years ago, because the profession at large has recognized the value of the remedy, and it is being employed by many practitioners. It is sad to learn that in some parts of the country the knife is still advocated, while electricity, when properly applied, can be used so painlessly and effectually. Recently, it has been observed, that a more certain method of killing the fœtus was by rapidly increasing, and then suddenly and quickly diminishing the current without interruption of the same, using a current from twenty to fifty milliampères.

I do not know why the surgeons of New York do not take more kindly to electricity for the cure of extra-uterine pregnancy, unless, by its use, operations are taken from them.

Dr. Thos. H. Manley: A woman, four months pregnant, fell on a plank while crossing the sidewalk. Great pain, with signs of commencing peritonitis followed. Five days after the accident I saw the patient, with the attending physician. There had been an uterine hemorrhage, but no signs of any portion of the placenta having been discharged. The patient was in great distress, with a temperature of 104° F. After a careful examination a diagnosis of extra-uterine pregnancy, with the sac ruptured, was made. Operation was consented to, and the incision being made in the median line the knife went through a compact and dried blood clot. The placenta was found in the broad ligament; it was hard and dried, and easily removed. The fœtus was found under the intestines, in the neighborhood of the left kidney. No pus came through the drainage-tube; still, septic symptoms continued ten days, after which time she made a complete recovery. The fœtus and placenta are here photographed for your inspection.

In ectopic gestation, it seems to me, the first question we have to consider is, Is it possible to allow the mother to carry the fœtus to a viable period? I believe it is possible, and that it is our duty to do so. We have no moral or legal right to destroy the child's life. Modern surgery permits of safe operation in these cases. At the recent Congress in Berlin a French physician presented a mother on whom he had operated for extra-uterine pregnancy, and delivered her of a living child—the child died one week after delivery. At the same time a German physician presented both mother and child, he having delivered her by abdominal section—the fœtus being extra-uterine. Three things are necessary in normal pregnancy: First, proper vascular supply; second, protection for the fœtus; and third, facilities for its expulsion. Now in ectopic gestation the first two conditions are supplied. Just as a large dermoid cyst can be developed in the abdominal cavity, so it has been proved can a fœtus develop up to full term. The only agency wanting, then, is the facility to expel the fœtus. Art has provided for this in a free abdominal section. The danger from hemorrhage has, heretofore, intimidated the surgeon; but it should not now, as ample provision can be made which will effectually (forestall) this danger. Let us make a new departure and put our patient to bed, and endeavor to carry her along until a proper time, and then operate. I would like to inquire of Dr. McLean why operation was not performed in his case at the end of the nine months?

Dr. McLean: The fœtus was dead six weeks before I saw the case. It is my rule to examine all women under my care, whom I expect to confine, during the last months of pregnancy. Had that been done by the physician in charge of this case, the condition could have been recognized, and operation performed with some hope of saving the child's life; though I believe, in this case, the position of the placenta would have cost the life of the mother and child, if operation had been undertaken at the ninth month.

Dr. F. H. Daniels, in closing the discussion, stated it was not his object to defend Dr. Tait's operations, but

to bring out the possibilities of abdominal section for extra-uterine pregnancy. Outside of New York the operation is preferred to the use of electricity. Of course I cannot state what these tumors are which have been operated on as ectopic gestation, because I have not seen them. I am convinced there are numerous cases of ectopic gestation which rupture in the first weeks of pregnancy, and no evil results. In Janvrin's case operation might have saved the patient. There are no premonitory signs of rupture, and this has already taken place in the majority of instances before the physician is called.

In regard to the ethical side of the question I believe the mother's life should receive the first consideration. I do not think the histories of cases of this condition prove that anything could have been done to prevent rupture. The sac is generally ruptured in tubal pregnancy before the fourteenth week. If the tube is already ruptured, and there are no untoward symptoms, and the child is living and developing, then I could conceive that it would be possible to allow it to go to full term and by operation bring forth a living child. I have very grave doubts that Dr. McLean's case was one of tubal pregnancy.

DR. MCLEAN: There could be no reasonable doubt. I cut through the peritoneal covering of the sac, then muscular tissue one-half inch thick, and, finally, came upon the mucous coat. It is true the peritoneal coat was more or less adherent to the surrounding tissues; but the tube could be distinctly traced to the horn of the uterus. Double uterus was, probably, disproved.

DR. DANIELS: To sum up the matter, on discovering a case of extra-uterine pregnancy before the tenth or twelfth week, and no positive evidences of dangerous hemorrhage taking place, I would use electricity to destroy the growth of the ovum. Having succeeded, I would expect absorption and the patient's health restored. Otherwise, I would take into consideration the advisability of removing the mass by abdominal section. In case of rupture with threatening symptoms, I would operate as soon as possible, though these cases of operation for bad hemorrhage are not promising and are very difficult. If the ovum goes on developing at the end of the fourth month I would allow the patient to go through gestation; and, unless I could feel sure that the placenta was not implanted anteriorly in the sac, I would not operate to save the child, but would wait for evidences of amniotic absorption, as mentioned before, and then operate.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE MODERN MEDICAL STUDENT—SIR JAMES PAGET ON THE VALUE OF SCIENCE IN MEDICAL EDUCATION—OVERSIGHTS IN OBSERVATION—CAUTIOUS THINKING—DR. BROADBENT ON THE CLINICAL SIDE OF MEDICINE—AN EXAMINATION STORY—THE LATE DR. HANDFIELD JONES, F.R.S.

LONDON, October 11, 1890.

THE present is an age of evolution, and the process has affected the medical student at least as much as his contemporaries. Mr. Robert Sawyer and his colleagues, as depicted in the pages of Dickens, do not bear the remotest resemblance to the student of to-day. The latter, indeed, is a very different individual from his prototype of even some twenty years since. For this the increased severity of examinations is largely responsible. Nowadays students of medicine have to work, and work hard, even if they are only seeking to obtain the minimum qualifications. Not only with regard to work, but also in regard to play, there is a great change for the better in the modern student. Rowdyism may be said to have disappeared — certainly as regards the average student. Athletics, æsthetics, music, and literature attract a large number of votaries, while many devote themselves almost entirely to their work except in vacation. Anyway, if the student of to-day is not all that he should be, it is certainly not from any lack of good advice. I referred to some of this last week, but have by no means exhausted the stock of wisdom poured forth at this season for the benefit of the commencing student.

At Liverpool the winter session was opened on Saturday last with an address by Sir James Paget. He remarked that he that ceased to gain knowledge was always losing it, and he that was not a student while in practice was sure to become less fitted for his work every year that he lived. Students should make the best use they could of the teaching of the sciences in the colleges, for making them, as far as possible, scientific practitioners and students in after-life. We heard a good deal said by some that science was the only way to success; by others that practice was the only way to what was right. After watching for a great many years he was disposed to tell all students—and he thought the rule might hold good for others besides those in medicine—that both should be worked together. Neither taken alone was enough and sufficient for all that might be done best in life. There was, indeed, a great deal of medical knowledge which could be learned only in practice, but there was not one part of that which could not be learned as well by a scientific student as by anyone else, and there was a great quantity of knowledge to be applied in practice which could only be derived from scientific knowledge, and the range of that class of knowledge was every year increasing as the application of the sciences became more abundant in the practice of medicine as they did in every calling of life. In scientific studies might be acquired habits of mind for which they were, he did not say alone sufficient, but far better than any other pursuits that might be named; and here, too, the mingling with men who were pursuing science for other pursuits was especially advantageous. In ordinary talking men seemed to think that careful observation was one of the easiest things in the world, and there were some who spoke of it as if they themselves had never overlooked anything of importance in their lives. Study any science, and one could see examples of the opposite in every page. It would be a very useful book if someone would write—not a history of discovery, but a history of the oversights.

Sir James Paget said he was lately much struck, when walking on moors in Yorkshire, to find abundance of the sundew (*Drosera rotundifolia*). In his early student days, he said, he used to study botany on the broads of Norfolk, and saw—what everybody else did—that it caught flies and that flies hung upon its leaves. But he did not observe what Darwin had done—that it not only caught the flies, but that it entangled them; that it clasped them in its tentacles, and held them till it had slowly but surely digested, absorbed, and lived upon them; for that indeed it surely did. That which was now obvious to every man was exposed to the sight of all the great naturalists for centuries past; but not one of them observed it, and it was reserved for the keen perceptive powers of Darwin to find out that which might have been obvious to every man's mind. That might be told of every month of our lives. There was another faculty to be as carefully cultivated, and that was cautious thinking. John Hunter used to say, "Do not think, try." He would add on the words "Be patient, be accurate." It might be well for us to keep in mind the three words, but he might read them with this paraphrase: "Do not think that you are likely to state what is true in science; test for it by observation." We should look, for example, at Pasteur's work, or at the marvellous application of it by Sir Joseph Lister.

Dr. Broadbent, of London, gave the opening address at the Yorkshire College, Leeds, and took for his subject "The Clinical Side of Medicine." There was a very natural tendency, he said, on the part of students to suppose that the main purport of ward work was to acquire

a knowledge of physical signs. This might be pursued too exclusively. Familiarity with the physiognomy of disease was also absolutely essential, and would, indeed, be more useful to his hearers and their patients than that they should be good auscultators. Sometimes the look of a patient told you his whole story. You might read in the face of the sufferer typhoid fever, or pneumonia, or acute rheumatism; and you might read more than this—you might say he would do well or badly, would succumb without an effort, or would make a good fight for his life. When pulse and temperature and physical signs and urine had told all they could, you might see by the expression of the countenance that there was something behind which made for good or evil. Knowledge of this kind could not be conveyed in books or imparted by a teacher. Books and lectures could, it was true, tell the student what to look for, but he must look for himself, and the moment he entered the hospital he should make it an object to fix in his mind the indications of disease apparent in the face. Students should say to themselves, when they first saw a case, "Now what is the matter with this man?" and every time they saw him later they should say to themselves, "Does he look better or worse?" When in practice they would have to answer this question, both to themselves and the friends, every day, and the confidence they inspired (and indeed their usefulness) would depend greatly on the promptitude and justice of their answers. Carried into the region of physical signs the habit of noticing carefully every point which could be made out by vision was a gain of great value. While speaking of physical signs he would say that it was always well in diseases of the lungs to examine the sound side fully and carefully first, so as to establish a standard of comparison. He would also remark that in auscultation—whether of lungs or heart—it was not only what we heard that was important, but what we did not hear. It would conduce to clearness of comprehension if from the first students distinguished between facts of observation and the inferences based upon them. They had no business, for instance, to put down in their notes that a systolic mitral murmur was present. The patient should be examined day by day, as if they had never seen him before, and they should set down their observations without reference to what they had written previously. They would probably find now and then that they had contradicted themselves flatly. He should be disappointed if they did not; no lesson could be more useful.

Dr. Broadbent then proceeded to speak of examinations, and narrated an incident of his own career which certainly "takes the cake" among recent examination stories. When he went up for the examination at the College of Surgeons (1857), he said, it was *viva voce* only and lasted just an hour—a quarter of an hour at each of four tables. At the fourth table he was questioned on the subject of psoas abscess. In those benighted days, said Dr. Broadbent, the treatment recommended was gradual evacuation by small valvular punctures, and it so happened that he had had an apparently successful case in the practice of the gentleman to whom he was apprenticed. He therefore described this method, and was asked, somewhat sharply, if he had ever seen a case so treated, when he replied "Yes;" if he had ever seen one get well? Again he said "Yes," upon which his examiner said, "I don't believe you." To the next question he made no answer, and, when it was repeated, he still remained silent. The examiner now got angry; he was himself already so, and leaning back in his chair said that as the examiner doubted his word he did not propose to answer any more of his questions. Dr. Broadbent remarked that he did not remember the details of the scene which ensued, but said he recollected well that he derived much comfort and encouragement from the fact that the colleague of his adversary got up from the table and walked to the window looking over Lincoln's Inn Fields, where he could see his sides shaking with laughter. Fortunately, he said, the other three tables saved him from rejection.

Another link with the past is severed by the death of Dr. Charles Handfield Jones, F.R.S., at the ripe age of seventy-one. He was educated at Rugby, where he came under the influence of Dr. Arnold, then head-master. On leaving Rugby the future physician proceeded first to the University of Cambridge, and subsequently studied in St. George's Hospital, London. Graduating as M.B. at Cambridge, in 1845, he became a Fellow of the Royal College of Physicians in 1849, and was elected a Fellow of the Royal Society in 1850, at the early age of thirty-one. In the following year he became one of the original members of the staff of St. Mary's Hospital, London. He became full physician in 1864, and retained the appointment for the full term of twenty years. Dr. Handfield Jones was an indefatigable worker, and not only in original work but also in the daily routine of clinical work put forth his best strength. Many of his old pupils will remember his almost daily visits to the hospital and the enormous pains he expended in taking notes with his own hand of most of his cases. Respected by all who knew him as a scientific and Christian physician, Dr. Handfield Jones was certainly not one of the least distinguished of Arnold's pupils. Much of Arnold's influence remained with him through life, and to his principles—if not directly to his teaching—Dr. Handfield Jones would himself have acknowledged that much of his success was due. His own personal influence as an exponent of those principles was not slight. I should add that he was no recluse, but fond of manly exercises and an ardent mountaineer till within a few years of his death. Two sons follow him in the profession, and one of these is a member of the staff of the hospital where Dr. Handfield Jones worked for so many years.

LETTER FROM CARACAS, THE CAPITAL OF VENEZUELA.

A MODERNIZED SPANISH-AMERICAN CITY—A RISKY RAILROAD RIDE—MEDICAL PRACTICE IN THE CAPITAL—THE MODEL HOSPITAL IN SOUTH AMERICA—LEPROSY IN VENEZUELA—SMALL OPENING FOR AN AMERICAN PHYSICIAN.

(From a Staff Correspondent of the MEDICAL RECORD.)

CARACAS, as everybody may not know, is the capital of Venezuela, and the most important commercial city of the republic. It lies in a beautiful valley, at an average altitude of 3,018 feet, its highest point (Pastora suburb) being 3,126 feet, and its lowest (the iron bridge over the river Guaire) being 2,889 feet above sea-level. It is distant from the Caribbean Sea but six and a half miles, as the crow flies, but the railroad leading to the seaport, La Guayra, is twenty-three miles in length, twisting and turning over the mountains in a most remarkable fashion in order to avoid too steep a grade. This railroad is rather interesting from a medical point of view, in that the services of a surgeon are almost never required in case of accident. The road-bed is nothing but a scratch along the face of the mountain, just wide enough to allow the narrow cars to pass, the outer rail being in many places not more than two or three inches from the edge of the precipice. When the train leaves the track, as it has done two or three times, it jumps down the almost perpendicular side of the mountain some thousand or more feet, and that is the end of it; there is no need of surgeons or of wrecking-trains, everything is effectually disposed of, and the track is clear for the next train. There is a beautiful simplicity about this that charms the traveller—after he has safely passed over the road—although the thought of it may not be reassuring while he is in transit.

Caracas is a city of some 75,000 to 80,000 inhabitants. The houses are all of brick or adobe, one story in height, and built about a central court, or "patio," where are found usually fountains and numerous flowering plants and fruit-trees. All the rooms of the house open out of the patio, and the only light and air which they receive

come through the door, for windows, except in the rooms facing the street, are unknown. The climate is both good and bad. There are no extremes of temperature, such as are familiar to the dwellers in the North, but such excursions of the mercury as there are may sometimes be seen within a period of twenty-four hours. The thermometer may indicate 80° F. in the middle of the day, while at night and in the early morning the temperature may fall to 65° or even 55° F. Summer clothing may be worn the year round, but it is seldom safe to leave the house in the evening without being provided with a light overcoat to guard against a sudden fall of temperature. There is usually more or less rain during seven or eight months of the year, and during this period the air is nearly always damp. As a result of this, catarrhal affections are very prevalent, and even pneumonia is not unknown, though it is comparatively a rather rare disease. Pulmonary phthisis is, however, rather common. Liver troubles, especially among the foreign population, are of more or less frequent occurrence, but the ordinary tropical diseases are rare. A nondescript fever of mild type is common enough, especially when one has been soaked in a hard shower, but severe malarial fevers are infrequent. The city has been visited by yellow fever on several occasions, but it is now many years since any but sporadic cases of this disease have been seen. Measles and scarlet fever are of frequent occurrence in children, and diphtheria affects both children and adults to a considerable extent. Diarrhœa and dysentery are frequent causes of death in children. Rickets is said to be common; but either this is an error or else the disease is very fatal, for one sees in adults few cases of crooked legs or of other deformities usually referred to rachitis as a cause.

Cigarette-smoking is universal, the schoolboy of ten or twelve years being as great a devotee to the habit as the man of sixty, yet the practice seems to lead to no serious results, and affections of the naso-pharynx are no more common than one would expect to find in a damp climate where there are variations of twenty or twenty-five degrees Fahrenheit within a period of a few days, or even of a few hours. Eye troubles seem to be quite common, and a stranger is struck with the number of blind people in the streets. The blindness may possibly be the result of ophthalmia of the new-born, for cleanliness among the lower classes is a rare virtue, and gonorrhœa is common in male and female alike.

There are about one hundred and fifty practising physicians in the city, and most of them are kept moderately busy, though they are by no means overworked. The proportion of physicians to the population is about as one to five hundred—rather better than it is in New York and other cities in the United States, though not as good as it seems, for the larger part of the population is very poor and unable to pay living fees for medical attendance. The usual charge for an office visit is one dollar, and for a visit to the patient's house two dollars.

There are several hospitals in the city, one general hospital and a military and woman's hospital. There is a small orphan asylum and a larger one is building. There is also a leper hospital near the city, where there is quite a colony of these unfortunates, the disease being not at all uncommon in this part of Venezuela. A very large general hospital, The Varas, is now in process of construction, and will soon be ready for the reception of patients. It was started by Rojas Paúl, who was Guzmán Blanco's successor in the presidency of the republic, and was originally intended to accommodate one thousand patients; but the plans have been altered somewhat, and there is now provision for only four hundred and forty beds. The general plan of the buildings is that of a central quadrangle, containing the doctors' quarters, operating-room, kitchen and administration buildings, and two wings, of ten pavilions and a chapel each, intended for male and female patients. The wards are one story in height, and have each twenty-two beds, besides a bath-room, water-closet, nurse's quarters, and drug-closet. The pavilions are separated from each other by gardens about twenty feet wide, containing flowering tropical plants, and they all face a large court where are fountains, flowering shrubs, and fruit-trees. At the end of each court is a very pretty little chapel. The hospital is very complete in its appointments, and the Caracans intend to spare no pains to make it the model institution of its kind in South America.

Caracas has a plentiful supply of water available for use, but the means for its distribution through the city are not very effective, and the inhabitants are so wasteful of it that at certain times in the day little or none can be obtained. The sewerage is poor, but the government is talking of building new sewers that will be amply sufficient to remove all the waste. The streets are rather poorly paved with small cobble-stones, but are kept passably clean. They resemble New York streets in that they are being constantly torn up by workmen laying gas-pipes, telephone wires, and the like.

Does Caracas present a good opening for a young physician from the United States? No. There are already more native physicians than are needed to alleviate the ills of the inhabitants, the fees are small, many of the people being too poor to pay anything at all for medical attendance, living expenses are very high, and the number of foreign residents who would employ a North American doctor is small. The dispensary evil has already taken root here, and promises to grow rapidly to large proportions, especially when the new hospital, with its out-door poor department, is completed.

THE "TEMPTATION OF JOHNS HOPKINS."

To the Editor of the Medical Record.

Sir: Pardon me if I suggest that the statements made in your editorial of November 15th, rather wittily entitled "The Temptation of Johns Hopkins," sound almost as if "made with intent to deceive." The generous gift of $100,000 is pronounced "ineffective," as if the university had announced an intention of immediately opening the projected medical school upon this foundation alone. But it is perfectly well understood that the school will not be opened until the full fund of $500,000 is collected. How, therefore, can the acceptance of the first fifth of this sum defeat the "expectation that the school was to start to work with a high-class equipment?" It is now, as ever, expected that the Johns Hopkins school "will draw the best educated and most ambitious students;" but these will come from among women as well as men. It will no longer be possible to absolutely deprive the best intellect in the one sex of the necessary opportunities which are freely accessible to the most mediocre capacities in the other. The universities of France, Switzerland, Italy, Denmark, Norway, Sweden, and Belgium have *not* found their "prestige impaired and their usefulness limited" by the admission of women to their just share in educational privileges. Why should the Johns Hopkins University be more impeded than they?

A richly endowed university is able to rise above the petty business calculations which so often "impair the prestige and limit the usefulness" of medical schools whose professors are paid out of the fees of the students. It is well known that precisely the same dread of losing students which has sufficed to exclude women from medical schools, has also sufficed to keep down in them the standard of medical education. There is no case on record in which the admission of women has lowered the standard. When women bestow money upon colleges devoted exclusively to men, their action is applauded as generous and public-spirited. Here one woman alone has given $50,000, from her private fortune, for the intellectual benefit of her own sex, and others have

worked and given with equal disinterestedness in proportion to their means. But now this public spirit is belittled as "persistent nagging!" How do Miss Garrett and Miss Hovey and their friends differ in spirit from John Harvard and Ezra Cornell? To John Garrett's influence was largely due the original direction of the Johns Hopkins bequest. It is nobly fitting that to John Garrett's daughter should be chiefly owing the just extension of the Johns Hopkins privileges to women. When there are a sufficient number of university medical schools open to women, isolated medical schools for women (as indeed for men) will fall into their natural position of intermediate or preliminary schools—feeders for universities—analogous, as Ex-President White has happily proposed for the smaller colleges, to the public schools of Eton and Rugby in their relations to the universities in England, or the gymnasia to the universities in Germany. Hence $100,000 given to one of these schools, though greatly needed, would not in the least degree supersede the necessity for the admission of women to such a university as the Johns Hopkins. The ladies' committees which are still working for the Johns Hopkins Medical School Fund would do well to use the ungenerous editorial in the RECORD upon their circulars. It well indicates a spirit that the world may hope to have seen disappear, when women shall have had the freedom of universities for a century.

MARY PUTNAM JACOBI, M.D.

NEW YORK, November 16, 1890.

[Our talented correspondent has ably presented her side of the argument. We are always pleased to hear from her on these questions.—ED.]

SCHOOLS AS SOURCES OF INFECTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In an editorial article on "The Prevention of Scarlet Fever and Diphtheria," in to-day's number of your paper, I am quoted as having proposed the appointment of school-physicians, which should examine the throats of the attending children every morning.

This is perfectly correct, yet this proposal was not made in an article headed "The Prevention of Scarlet Fever and Diphtheria," but in an editorial in the February number of the *Medic. Monatsschrift* of 1889. This article was headed "Schools as Sources of Infection," referring in particular to the public schools of New York. My proposal reads: "Discard lessons in physiology, give the children a longer recess at noon, and—last but not least—appoint one or more physicians for each school, to examine the throats of all children every morning. The expense would be light, and the result (with a non-political selection of physicians) necessarily an excellent one."

A United States Senator saw this article at the time, and wrote, asking me to assist him in drawing up a bill for legislation, which I refused to do. Since then this proposal has been repeated in medical literature without giving me credit for originality, so that at last I took occasion, at a meeting of the Pediatric Section of the International Medical Congress in Berlin, to thank the reader of one of the papers for having so carefully repeated my proposal there, written by me and read by him in my above mentioned article, a year and a half ago.

The MEDICAL RECORD was the first journal to give me credit for this idea, but it gives me more than I ought to have. The particulars as to the sums of money needed do not come from my article. I also never proposed to let children use their fingers as tongue-depressors, nor would I, for it might lead to overlooking many incipient cases of diphtheria in the lower pharynx.

By giving these lines a place in your esteemed journal, you will assist me in refusing such credit as does not belong to me. Respectfully yours,

A. SEIBERT, M.D.

137 EAST NINETEENTH STREET, NEW YORK.
November 15, 1890.

ANOTHER QUESTION OF PRIORITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the issue of your journal of November 8th, there appeared an article by Dr. W. E. Forest, of this city, describing a new appliance for putting on plaster jackets, without the Sayre suspension apparatus.

The first seven paragraphs are devoted to the introduction, the disadvantages of the Sayre method, the advantages of the new plan, and in the eighth he discusses the construction of "my apparatus."

Those of your readers who examined the new device may be interested to know something more of the history, of the labor and travail with which the doctor brought forth this progeny. The conception took place in my office, when the doctor called to borrow my suspension apparatus, which was loaned him, and, in addition, he was given a detailed description of a new contrivance of my own, besides a drawing of it.

Its advantages in putting on the plaster-jackets, especially when working alone, were pointed out with the enthusiasm of an inventor, and which he has so faithfully reproduced for the readers of the MEDICAL RECORD.

It had been shown to two others only in this city—Professor Louis A. Sayre, and the late lamented Dr. Louis Hall Sayre; and to only two outside of the city—Dr. D. B. Cotton, of Portsmouth, O., and my nephew, Dr. Louis B. Smith, of Pennsylvania.

The description and drawing were given him in the summer of 1889, and in the fall he presented it to the New York Medical Union as his offspring. The information of his claiming the waif did not reach me until after the publication of the article, and could not, therefore, be disproved.

Under the circumstances the profession will not fail to appreciate the advantages of inventing from a plan, a model, or drawing, appropriated and lying before you, especially if the inventor has a description with the draft. Invention then becomes as easy as the friends of Columbus found it to stand an egg on end after seeing him do it.

In closing his communication to the MEDICAL RECORD, the doctor insists that to him belongs the credit of the "cross-bar for the child's hands, and the leaning position so as to get good extension."

The writer does not object to his having all the credit for his improvements (?); but does object to the form of his presenting them to the profession, which by inference implied that the important factor of good extension had been overlooked.

It had been explained to him that the frame should rest on two supports of equal height, and the upper extremity secured by a roller-bandage passing under the arms and around the cross piece, and secured to it.

One of the family is then instructed to make slight or considerable extension by the feet, as the particular case may require. If more extension is needed, or more accurate measurement is desired, the feet should be secured by pieces of adhesive plaster and a roller (after the ordinary method), and to the plaster attach a rope and the pulleys; connect these to a pair of common spring scales fastened to the wall, on a level with the frame. The force can then easily be measured and maintained until the plaster has set.

These are mere details which anyone with the mechanical skill to put on a jacket can easily extemporize.

The easiest possible position for the patient, and for the operator, is thus attained, which is the prime motive of the device, and which object is neutralized by Dr. Forest's improvements.

One important factor is omitted as yet: the child should be placed on the cot with the face downward, after adjusting the shirt, and before the extension is applied, and the points of portuberance carefully padded and fastened. The patient is then turned over and the jacket finished in the usual manner.

In conclusion it must be stated that it is an unpleasant duty that is thrust upon me, that of charging a member of the profession, and a friend of many years, with appropriating a device and palming it off on the profession as "my apparatus." DANIEL BROWN, M.D.

85 EAST TENTH STREET, NEW YORK.

FOOT-AND-MOUTH DISEASE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Till the gentleman who reported the discussion of my paper on "Foot-and-Mouth Disease," etc., on December 1, 1887, admits that he reported inaccurately what Professor Law and the other gentleman said upon the subject in question, I shall hold to the opinion I expressed in my reply to Professor Law's "Criticism."

Respectfully,

JOSEPH WILLIAM STICKLER, M.D.

THE DANGERS OF POWERFUL ELECTRO-MOTIVE FORCES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue of November 1st there appears an article entitled "Electrolytic and Other New Uses of Storage Electricity," by Dr. Robert L. Watson. This article may exert a decidedly injurious influence if the statements contained therein are allowed to pass uncontradicted. If practising physicians who possess powerful galvanic batteries were to pass currents of one hundred ampères through their patients, as Dr. Watson claims he did, or even the one hundredth part of this current, the number of cases of electrocution would, in all probability, be considerably augmented.

Dr. Watson cites three cases. In two of these he claims that one hundred ampères of current were used for a period of five minutes. In the third case ten ampères of current were passed on two occasions for ten minutes each time. To the physician who comprehends the significance of the term "ampère," these statements will, of course, be appreciated at their proper value. But there may be many who may be tempted to emulate Dr. Watson, and attempt to remove nævi, warts, etc., by using currents of tremendous electro-motive force in order to obtain a great number of *milliampères*, thinking, perhaps, that the word "ampère" is a typographical error, and that "milliampère" is the word the author intended to use.

Many physicians possess batteries that will give a current of one hundred milliampères through one thousand ohms of resistance. The resistance of nævi, warts, etc., does not approach one thousand ohms. It is therefore quite possible for an operator to suddenly pass a current of high voltage through his patient in order to obtain the one hundred milliampères of current which he supposes are essential for the proper treatment of the case, but which, on the contrary, would be attended with great danger, especially if the application was made to growths situated on the head or face.

Dr. Watson's error consists in supposing that what is termed a "one-hundred-hour ampère storage cell" gives a current flow of one hundred amperes through any part of the body; whereas, the fact is, one storage cell, no matter what its size may be, even with only the slight resistance interposed by nævi, warts, etc., would barely indicate one milliampère.

"It is curious," says Dr. Watson, "but nevertheless a fact, that when a milliampère metre was included in the circuit with the nævus no current was indicated." The fact is that the current flow from one storage cell through the nævus was not equal to one milliampère, hence the needle of the milliampère metre was not deflected. One hundred ampères of current passing through his metre and his patient would probably have destroyed both of them simultaneously. Dr. Watson's plan of treatment is excellent, and if properly performed will do all that is claimed for it. From three to four cells of an ordinary galvanic battery, employed as Dr. Watson recommends, will usually give satisfactory results.

I have hoped that Dr. Watson would correct his error in a subsequent issue of the RECORD, and I have therefore delayed my letter till the present time, but the danger of allowing such erroneous statements to pass unheeded is so obvious that it does not seem to me advisable to keep silent.

Very truly yours,

GRÆME M. HAMMOND, M.D.

November 15, 1890.

THE NUBILE AGE AND EARLY MARRIAGE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: When I saw the RECORD'S comments on the above subject in the issue of November 1st, I hoped the next number would contain a response from one of your many able contributors. That the discussion before the Calcutta Medical Society should have elicited no scientific, manly, or indignant protest, so far from being construed favorably to child-marriage, will, perhaps, be considered by very many of your readers as indicative of a *lapsus mentis* on the part of the honorable members of the society, in view of the admission that "Cases of death from premature sexual intercourse (in India) are by no means rare, while the local injuries are often serious and permanent."

When "the Levite went to Bethlehem to fetch home his wife,"[1] and when his host "brought her forth unto the sons of Belial," to whose diabolic lust she was sacrificed, "because they would not hearken unto him," the judgment of Heaven, as understood by the Israelites, could not be satisfied until the power of the lustful and haughty Benjaminite was humbled, though to do so required that tens of thousands of the men that drew the sword should be "destroyed down to the ground."

With every advantage of climate and soil, with a country presenting "an epitome of the whole earth," an offshoot from the same Aryan stock as ourselves, who can doubt that the chief cause of imbecility in the Hindoo is their insensate and cruel treatment of their women—an imbecility permitting, for over a century, a handful of Englishmen to rule over their teeming millions.

History repeats itself, and there seem to be indications that, as of old—but in a higher form—the functions of priest and physician may again become blended.

Is it safe or practicable to divorce morals and medicine?

The wretch who, despite the struggles and entreaties of his helpless child-wife, causes her "death from premature sexual intercourse," is a more monstrous villain than if, in sudden anger, he should plunge a dagger into her heart. "*Facilis descensus Averni.*"

Yours, respectfully,

W. F. MORGAN, M.D.

LEAVENWORTH, KAN.

Remarkable Fecundity.—Dr. J. De Leon, of Ingersoll, Tex., has reported a recent experience with the delivery of quadruplets. The first child had its own placenta; the second and third had their placenta; the fourth had also a placenta. They weighed at birth in the aggregate nineteen and a half pounds without clothing—first weighed six pounds; second, five pounds; third, four and a half pounds; fourth, four pounds. The mother is a blonde, about thirty-six years old, has given birth to fourteen children, twins three times before this; one pair by her first husband. She has been married three years, and has had eight children in that time.—*Dietetic Gazette.*

[1] Judges xix. 20, 21.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 9 to November 15, 1890.

WALKER, FREEMAN V., First Lieutenant and Assistant Surgeon, Fort D. A. Russell, Wyo. Granted leave of absence for one month, to take effect on or about the 15th instant. S. O. 85, par. 3, Department of the Platte, November 11, 1890.

COWDREY, STEVENS G., Major and Surgeon. By direction of the Secretary of War, the leave of absence granted in S. O. 112, Department of Arizona, October 24, 1890, is extended fifteen days. S. O. 263, Headquarters of the Army, A. G. O., Washington, D. C., November 10, 1890.

MCELDERRY, HENRY, Major and Surgeon. By direction of the Secretary of War, the extension of leave of absence on account of sickness, granted in S. O. 214, September 12, 1890, from this office, is further extended two months on surgeon's certificate of disability. S. O. 263, par. 28, A. G. O., Washington, D. C., November 10, 1890.

ALEXANDER, CHARLES T., Lieutenant-Colonel and Surgeon, and MIDDLETON, JOHNSON V. D., Major and Surgeon. By direction of the Secretary of War, are appointed members of a board of officers, appointed to meet at the call of the senior officer thereof, at the rooms of the Board of Engineers, Army Building, New York City, to examine such officers of the Corps of Engineers as may be ordered before it, with a view to determining their fitness for promotion, as contemplated by the Act of Congress, approved October 1, 1890. S. O. 261, par. 4, A. G. O., Washington, D. C., November 7, 1890.

NORRIS, BASIL, Colonel and Surgeon, and STERNBERG, GEORGE M., Major and Surgeon. By direction of the Secretary of War, are appointed members of a board of officers, appointed to meet at the call of the senior officer thereof, in San Francisco, Cal., to examine such officers of the Corps of Engineers as may be ordered before it, with a view of determining their fitness for promotion, as contemplated by the Act of Congress, approved October 1, 1890. S. O. 261, par. 5, A. G. O., Washington, D. C., November 7, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 15, 1890.

OWENS, THOMAS, Surgeon. Ordered to the Museum of Hygiene, at Washington, D. C.

MARTIN, H. M., Surgeon. Detached from the Receiving-ship Wabash, and ordered before Retiring Board.

RIXEY, P. M., Surgeon. Continued in charge of Naval Dispensary at Washington, D. C., until November 20, 1891.

GREEN, E. H., Passed Assistant Surgeon. Promoted to Surgeon, November 10, 1890.

SMITH, HOWARD, Surgeon. Placed on the retired list, November 10, 1890.

Good Effect of Darkness on Nutrition.—Dr. S. Klein, has made a communication to the Medical Association of Vienna on the effect of darkness in a case of retro bulbar neuritis, in which, after the author had ordered treatment in the dark, marked increase of appetite and nutrition occurred, both of which had been previously much impaired. He confirmed this observation afterward by a whole series of experiments, and consequently suggests treatment in the dark for cases in which it is desirable to increase the nutrition and appetite.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 15, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	21	10
Scarlet fever	95	7
Cerebro-spinal meningitis	1	1
Measles	183	11
Diphtheria	84	27
Small-pox	0	0
Varicella	1	0
Pertussis	1	0

The Berlin Sewerage System.—The following facts concerning the Berlin sewerage system, which Virchow praised so highly in his opening address to the International Medical Congress, are communicated by Dr. Hobrecht, Municipal Councillor on Public Works. Berlin is divided into twelve radial systems, of which systems 1 to 7 have already been at work for some time. System 8 is in full course of construction, and will be at work in the course of this year. System 9 is also in course of construction. System 10 is almost finished. System 11 is still only a project, but system 12 will be finished in 1891, or at latest in 1892. The question whether and in what measure the sewerage system has improved the health of the population is answered by Dr. Hobrecht thus: "It is certain, and has been officially stated, that infections diseases, especially typhoid fever, have decreased; it is probable, however, that in the present state of science no one is able to maintain that this is due to the sewerage system, while the time since the completion of the works has been too short to admit of an empirical inference in this direction. Hygiene, on the other hand, adheres to the principle that it is of importance to promote cleanliness in water, air, and soil. The sewerage system of Berlin has satisfied this demand in a degree partly attained in some other cities, wholly in none. No other city, however, of more than a million inhabitants can boast of the achievement that the water of the river that flows through it, especially if so small as the Spree, is clean, and that the same may be said of the water of the main ditch, which, after the removal of the suspended and dissolved impurities by irrigation and drainage, carries off the waste water of nearly half a million people."—*The Lancet.*

Poor Condition of Our Public Baths.—The condition of the public baths in this city shows the great importance of having all the sanitary arrangements, controlled by our public authorities, under the direction of competent medical inspection. It has been recently found that all of the public baths, except the Battery, which have been daily patronized by thousands of the poor, are so unhealthy that the bathers are liable to contract in them not only severe forms of ophthalmia, but other diseases. The water has been found not only filled with more or less noxious particles, but the bottom contained unhealthy deposits. This can hardly be avoided, except in such exposed places as the Battery, under the present system of sewers and docks, where the filth pouring out from the sewers collects in and about the slips and docks. The Battery is the only point along the line of the densely populated city which escapes the wash of filth borne down by the tide of both rivers and washed out to sea, and to this point at present it is clear the salt water baths should be confined. Fresh-water swimming baths, free to the poor, could easily be established, from the large amount of Croton water now at our disposal, in different parts of the city where there would be no danger of contracting diseases. If a portion of the enormous sums of

money now expended in public and private hospitals and infirmaries were devoted to the prevention of disease by securing better sanitary conditions, our city, instead of ranking as one of the most unhealthy cities in the civilized world, would soon take its proper position as the healthiest. When the people insist that our sanitary affairs, including sewerage, docks, and streets, shall be taken out of the hands of mere politicians and put in those of scientists who understand their business, this end will be accomplished.—*New York Medical Times.*

Longevity.—When the French Ministry, some twenty-five years ago, issued a circular to all its préfets making inquiries as to the conditions most favorable to longevity, all the reports agreed in naming a well-to-do condition of life as most important, if not quite indispensable. It should also be borne in mind that the most wonderful cases of longevity are almost invariably reported from countries where verification of the asserted facts is impossible. For instance, *The Lancet* some time ago quoted the case of an old man of Bogota, San Salvador, who "confessed to being one hundred and eighty years old, though his neighbors believed him to be much more." With no possible check from authentic records, his kindly neighbors might well have given him an additional century with impunity. Something of this kind doubtless happened in the case of an old native of Bengal, who was reported by Dr. C. W. de Lacy as having attained the antediluvian age of three hundred and seventy. Dr. de Lacy reports several cases as to which we recommend a due degree of doubt. A certain Thomas Whittington, who died in 1804, at the reputed age of one hundred and four, never drank, we are seriously told, any liquor but gin, but of that fiery compound he consumed from a pint to a pint and a half daily. This is probably more than any of the doctor's readers will find it easy to swallow! Walter Savage Landor tells of an old man whose own testimony, if true, proved him to be twelve or thirteen years over a century, but who would only own to eighty-nine, like some young ladies who object to passing thirty, and somehow manage to remain forever at the age of twenty-seven. On being told of a man in Russia who was one hundred and thirty-two years old, this comparative youth of eighty-nine replied, "Very likely he is more, but won't own it; people when they are getting a little on in years don't like to say anything about it." It is well known, however, that a contrary disposition generally shows itself, and people who have attained to a very old age develop an ambition to be thought rivals of Methuselah. Personal appearance is no criterion to judge by. The popular expressions, "aged," "very aged," often signify merely white hairs or baldness, or paralysis, quite irrespective of the number of years the persons so described may have lived. To parody the remark on Lord Thurlow's face, it may be said that nobody ever was so old as they look.

The Sanitary Value of Slack Water.—J. M. Safford publishes, in the *Tennessee State Board of Health Bulletin*, a paper upon the influence of slack water navigation upon the public health. Slack waters form a series of pools in the course of a stream. The water is not stagnant, as in a pond, but the flow is regulated by the supply; the level remaining near the same point at all times. By this means the uncovering of areas usually under water, and the occasional flooding of low lands usually dry, are in some measure prevented. Low, marshy spots near the stream are also covered; and from all these it results that the most fruitful sources of malaria are shut off. If the water be used for drinking purposes, the slack waters act as subsiding reservoirs; and, as fresh-water plants grow more luxuriantly in them than in the shallow and rapid current of the natural channel, the water is purified by the action of both these agencies. Flushing is accomplished by heavy rains, and by the spring freshets. Analysis of the river and well waters at Zanesville, by Dr. Culbertson, showed that the river water was beyond comparison the purest; and the same writer states that the death-rate from malaria, pneumonia, and diarrhœa is now less than it was in 1869. Along the Shenango Valley the abandonment of the Erie Canal, and letting out of the slack waters, has resulted in a widespread prevalence of malaria, which has not disappeared after ten years, though the type of disease has been somewhat modified. Here, low tracts were uncovered which had for many years been under water, accumulating mud, laden with organic matter in abundance. The river water was not used for drinking, and the ague arose from emanations from the soil.—*Times and Register.*

Prince Bismarck and Mr. Gladstone on the Effects of Modern Education.—Two great authorities on social matters have lately expressed their personal opinion on the results of modern education as to its effects upon the well being of the population. Prince Bismarck thinks that higher education for the lower classes has been too widely spread, and in a recent conversation is reported to have said: "Over-education in Germany leads to much disappointment and dissatisfaction; in Russia, to disaffection and conspiracy. Ten times as many young people are educated there for the higher walks of life as there are places to give them, or opportunities for them, in the liberal professions, to earn a decent living, far less wealth and distinction. Perhaps it is not quite the right kind of learning, too. What good does it do them? When they have gone through it, in nine cases out of ten, there is nothing for them to do, and their learning is worse than a superfluity to them, for it makes them discontented—nay, miserable." Mr. Gladstone takes a different view, but believes that classical education should only be given to those likely to profit by it in after life. He is strongly desirous to promote physical and corporal education generally, and attaches much value to the training of the eye and the hand; for this purpose he urges that some branch of natural history should have a higher place in the modern theories of education than it has yet obtained. In these days, when many medical men see reason to believe that education in too many cases exhausts and injures the nervous system, in place of developing and strengthening it, it is interesting to know the opinion of great statesmen of experience. The question is a very serious one, and demands inquiry as to the effects of our educational system upon the brains of the young.—*British Medical Journal.*

Intestinal Calculus from Abuse of Vichy Water.—Dr. Loviot described, before the Paris Obstetrical and Gynecological Society last autumn, a case where he discovered a scybalous mass in the pelvis of a woman, aged thirty-two, who had been under his observation for over nine years. She suffered severely from constipation, and within five years spent 250 francs in the purchase of Vichy water powder. Besides drinking the powder in solution daily, she also took tamar, and administered to herself enemata. Defecation became very painful, leaving the sensation—not an illusion in her case—of a ball pressing on the perineum. Dr. Loviot succeeded in partially breaking the mass down by means of a blunt curette, then it was easily extracted through the anus without any laceration of the sphincter. The mass was as big as a small orange and very hard. The outer part consisted of dry fecal matter, infiltrated with salts. In the interior was a white calculous mass of salts. M. A. Guérin, in discussing Dr. Loviot's case, spoke of another where severe diarrhœa was caused by the scybalous body. The mass itself was so hard that it had to be broken up by placing against it the end of an iron gouge, the handle of which was carefully struck by a mallet. With care the fragments were extracted without wounding the bowel or the anus. The diarrhœa immediately ceased.—*British Medical Journal.*

THE PRESENT STATUS OF THE OPEN INCISION METHOD FOR TALIPES VARO EQUINUS.[1]

BY A. M. PHELPS, M.D.,

PROFESSOR OF ORTHOPEDIC SURGERY, UNIVERSITY OF THE CITY OF NEW YORK; PROFESSOR OF ORTHOPEDIC SURGERY, POST GRADUATE SCHOOL AND HOSPITAL, NEW YORK; PROFESSOR OF SURGERY, UNIVERSITY OF VERMONT; MEMBER OF THE NEW YORK ACADEMY OF MEDICINE, AND THE AMERICAN ORTHOPEDIC ASSOCIATION, ETC.; VISITING SURGEON TO CHARITY HOSPITAL.

SINCE publishing my first paper, in 1881, on the operation of open incision in club-foot, I have operated upon one hundred and sixty-one cases, which I desire to report upon at this meeting. At that time, and in a subsequent paper published in the "Transactions of the Eighth International Congress, Copenhagen," my observations were

FIG. 1.—Shows not an uncommon result following primary osteotomy. There had been a resection of the astragalus in one foot and cuneiform tarsectomy in the other. Photograph made of a case in the practice of an eminent European surgeon.

not extensive enough to enable me to speak with any degree of authority upon the subject. My convictions as to the advisability of the method, however, were strong, and upon theoretical grounds, sustained by a limited number of cases, with results, I advised the operation. Mature experience now enables me to correct, or I might say more clearly define, many points which at that time could not be made perfectly clear. I argued then for the operation. Now I desire to present a method which should govern all operative procedures in club-foot, giving to the operation its proper place in surgery. The difficulties which the profession have encountered have been the varied methods and operations which from time to time have been urged as the cure for all cases; and only after a personal application of the method or operation urged has the operator discovered that his ship of anticipation has been wrecked upon the rock of experience. Primary osteotomy, astragalus resection, cuneiform tarsectomy, open incision, and prolonged and interrupted traction with intricate machinery have all run the gauntlet of observation, and the roadside everywhere is strewn with lamentable failures.

Why should this be so? Simply that method, based upon some pathological fact and data of experience, has been ignored.

I do not at this time care to discuss the etiology and pathology of talipes varo-equinus. Permit me to say, however, that in all the pathological specimens which I have examined, the distortion of the soft part has been out of all proportion to the deformity of bone; and many specimens of severe deformity, which I have in my collection, show but slight bone-deformity, and that is confined chiefly to the neck of the astragalus, while in other specimens the os calcis is also deformed. These distortions, added to a great dislocation of the small bones of the tarsus, with changes in their articular surfaces, constitute the bone-deformity of talipes varo-equinus in a very large per cent. of cases occurring in children. Now, if these observations are correct, and we can with perfect safety to foot and life divide extensively soft parts, and secure useful feet in a short time, or as good results as can be obtained by any other method, are we justified in performing a primary osteotomy or resection of the astragalus? Clearly not, for the results after primary bone operations are no better. Failures are common, and the mortality is about five per cent., whereas in operations on soft parts there is no mortality (see Fig. 1).

And, then, are we justified in treating a case by instrumental means for years, when a moment's work with the tenotome or knife would shorten the period of treatment to as many weeks, with a result equally as good? Certainly not, if the patient will consent to an operation. The tinkering and fooling with club-foot with traction

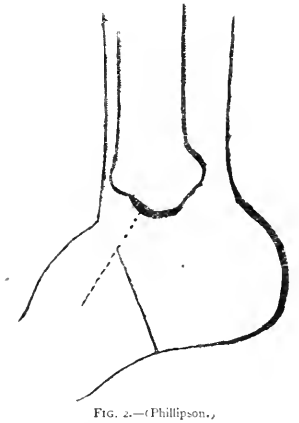

FIG. 2.—(Phillipson.)

machines, covering over long periods of torture reckoned by years, with all its failures, brought orthopedics of the past into disrepute. The surgeon and patient became disgusted, and out of the chaos and wreck we saw methods devised which shortened the period of treatment, and cured cases which chagrined the orthopedist on account of his failures. These methods of mechanics, when carried to extremes, as we have all been obliged to witness, degrades the orthopedic surgeon to the level of the orthopedist or mere instrument-maker, and one step farther carries him, with all his good intentions, within the vale of empiricism and quackery. Again, on the other hand,

[1] Read before the Tenth International Congress, Berlin.

the surgeon becomes impatient with all his cases and devises an operation. It proves serviceable in many cases, fails in others, until he finds himself blindly following his operation and not a principle, mutilating feet unnecessarily, and finally, in disgust over failures, abandons his operation.

A remedy for all this is a method, and nearly every

FIG. 3.—Specimen in the College of Surgeons, London, showing Arrangement of Tendons in Varus.

operation ever devised will find its legitimate place in surgery.

The method which I propose to govern the management of club-foot, requiring operative work, is this:

1. Exclude all cases which, by manipulation or force, can immediately or in a reasonable length of time be cured; then the following rule should be followed.

2. Cut the contracted parts as they first offer resistance, cutting in the order of those parts which first contracted when the deformity was produced.

The operator will then proceed, after strong manipulation or force is applied with a club-foot machine or with the hands (see Figs. 7 and 8), to subcutaneously divide, first the tendo-Achillis. *If the skin is not short*, subcutaneous tenotomy in the sole of the foot will usually suffice. *If the skin is short*, an open incision one-fourth the distance across the foot can be made, beginning directly

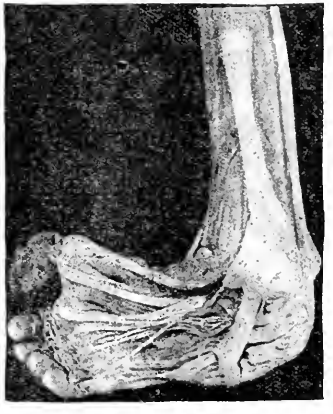

FIG. 4.—Specimen from the College of Surgeons, London, showing Muscles and Tendons in Varus.

in front of the inner malleolus and carried down to the inner side of the neck of the astragalus (see Fig. 2). Through this incision the following tissues can be cut, if they offer strong resistance, in the order given: (*a*) Tenotomy of tibialis posticus (see Fig. 3); (*b*) division of abductor pollicis (see Fig. 4); (*c*) division of plantar fascia through the wound; (*d*) division of flexor brevis muscle; (*e*) division of long flexors; (*f*) division of deltoid ligament, all its branches (see Fig. 5).

3. Linear osteotomy through the neck of the astragalus (see Fig. 6.)

4. Resection of a wedge-shaped piece of bone from the body of the os calcis, the point meeting the linear osteotomy through the neck of the astragalus. The foot will now swing to a straight position (Fig. 6).

This method of osteotomy is a correction of my former paper, in which the cuneiform section was taken from the cuboid bone.

In the management of club-foot it often becomes necessary for the operator to apply more force than can be done by the hands, not only during the time of the operation, but in the subsequent treatment of the foot as well.

In nearly all cases of varo-equinus there is a shortened condition of the ligamentous contraction posterior to the

FIG. 5.—Incision under the Skin for the Ligament (Phillipson).

ankle-joint, and also an inward rotation of the os calcis. In such cases there is not sufficient power in the hand of the operator to overcome the ligamentous contraction.

To fulfil all of these requirements, I have devised a machine which will be found invaluable. It can be used in the class of cases above indicated, and also for the purpose of placing the foot in the proper position before the application of the water-glass shoe and plaster-of-Paris dressing, or the application of any form of apparatus.

It consists of a combination of levers and screws so adjusted as to apply the force in the proper direction, varying from a single pound to one ton in force. The bed-piece (Fig. 7) is fastened to a table by means of the clamp, 15; 14 is an adjustable slide working upon the cross part of the bed-piece. After having etherized the patient, he is placed in the machine with his leg flexed, as seen in Fig. 7.

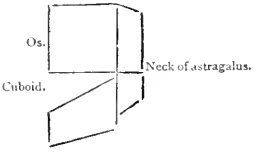

FIG. 6.

The slide, 14, is adjusted to prevent the leg from slipping. The straps 10, 11, and 12 hold the leg in a firm position on the bed piece; 16 is a fulcrum, into which the end of the lever, 1, is inserted for the purpose of making the pressure upon the os calcis by means of the pad. 4, 5 is the adjustable fulcrum into which the end of the other lever is inserted. The foot is attached to this lever by means of straps, 7, 8, and 9, Fig. 7, and 5, 6, and 7, Fig. 8. The straps, 5 and 6, are attached to the nuts, 4, 4, by turning the screws, 2, 2, which are held in the proper position by the framework, 3.

Any amount of force can be applied to the heel and instep. The jack can be adjusted to the lever as seen in Fig. 7, the strap, 7, passing around the foot, as is seen in Fig. 8, secures the toes firmly. The operator and his assistant turn up the screws, applying any amount of force

required. The operator now, with his canting lever, 3, in his hand, flexes and rotates the foot, breaking it across the adjustable fulcrum, 6, while his assistant holds the heel firmly with the other lever. As flexing force is applied

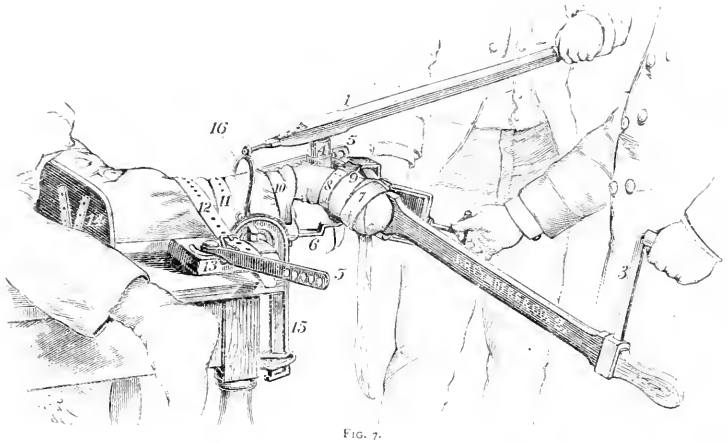

FIG. 7.

by the large lever, the leg is prevented from slipping by the adjustable slide, 14.

This machine will not only be found invaluable in all cases of club-foot, but more particularly so in those severer forms of club-foot requiring operation. The operator from time to time can adjust the machine and apply any amount of force, breaking ligaments which he would find difficult or impossible to cut. In the after-treatment of club-foot it will be found most useful.

The operator should not cease operating until the foot is super-corrected, otherwise a relapse may be looked for, beginning with manipulation, either with the hand or the club foot machine, or both, and concluding, if necessary, with extensive osteotomy, pursuing the order of procedure as recommended above. Failures occur because the operator concludes his work before the foot is straight, and guesses that he can correct the deformity left by proper after-treatment, which, as a rule, he cannot do.

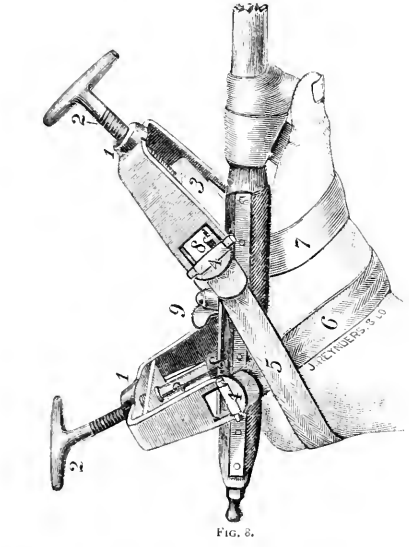

FIG. 8.

Another source of failure is bad dressing. The desire to use some pet splint, or devise some new scheme, accounts for the disappointment with results.

Failing to super-correct by operation and some worthless wooden or metal splint so adjusted as to make undue pressure upon the resisting foot produce sloughing or even gangrene. When the foot has been once super-corrected, it will then rest in proper dressings without resistance or pressure, and sloughing is never seen.

The Operation. — Prepare the foot by scrubbing, scraping, and antisepticizing with bichloride of mercury solution, 1 to 1,000, the night before. Carefully see that every detail of antiseptic surgery is followed at the time of operating. Then cleanse the foot with iodoform, 1 part; ether sulph., 8 parts. Apply the Esmarch bandage.

Keep up a constant irrigation with bichloride solution, 1 to 2,000 during the operation. After strong manipulation, either manual or instrumental, and subcutaneous tenotomy, make the open incision already described in Fig. 2, cutting in the order already suggested. Use strong force

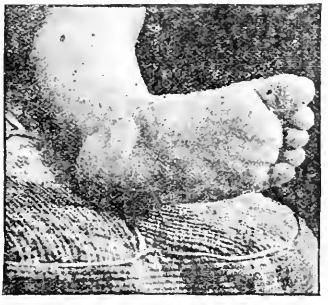

FIG. 9.

after each tissue cut. Nothing will be gained by dividing soft parts more extensively than suggested above. If the foot still resists and cannot be placed in a super-corrected position, linear osteotomy, and finally cuneiform resection, should be done (see Fig. 6). In two cases, in adults, I found it necessary to remove both cuboid and scaphoid bones. Open incision in children under one year of age I have never found necessary.

The Dressings.—Sponge out the wound, then apply, 1, Lister's protective, not rubber tissue; 2, antiseptic gauze, a large quantity; 3, antiseptic bandage; 4, absorbent cotton to knee; 5, over all a plaster-of-Paris bandage, holding the foot in the super corrected position, until the plaster sets; avoid making pressure either by dressings or twisting the foot too far outward; 6, remove the Esmarch bandage; 7, sling the foot to a nearly perpendicular position for six hours or longer. Organization of blod-clot usually occurs, but it is not essential to a good result.

My last cases were dressed as indicated, but the wound was filled with chopped-up fine cat-gut. Organization was perfect in each case. Fig. 9 shows scarring in a foot four weeks after the operation. Fig. 10 shows position of scar and appearance of the foot at the fourth

week; Figs. 11 and 12, the condition before and three weeks after the operation; Figs. 13 and 14, the deformity and the method of after-treatment by means of hooks and plaster one year after.

After treatment.—The plaster-of-Paris shoe; waterglass shoe and the hooks and plasters answer well. The hooks and plasters are well adapted to children over two years of age. Fig. 14 represents the plaster and hooks as applied to the feet, the bandages removed. The upper hook connects with a belt above the hips by means of a tape, which tape is secured to the side of the leg at the knee with a strap. The lacings between the hooks hold the foot in the normal position. The results of my series of cases and of those which I have compiled will be found in the table on p. 597.

Fig. 10.—(Gerster.

In conclusion, equino-varus, after any operation, or mechanical treatment, is quite likely to relapse. For months, and even years, the surgeon will need to carefully look after many of his patients. I have seen relapses following mechanical treatment which had been carried out for years, in every form of osteotomy, and

Fig. 11.

more particularly excision of the astragalus. In my travels through Germany I made casts of feet which had relapsed after these osteotomies in the hands of some of the most eminent and distinguished German surgeons, and the same observations are to be made in every country. An operation only straightens the feet; when this has been accomplished the treatment (and not until then can treatment be said to begin) is only commenced. The slight twist in the neck of the astragalus will not be found a serious obstacle in the way of cure, unless excessive, in which class of cases it should have been divided with a chisel at the time of operating.

What are the limits of the application of this operation? 1, Eliminate all cases which by the hand can easily be placed in a normal position; 2, eliminate all of those cases which can by subcutaneous tenotomy be perfectly relieved with accompanying proper after-management. Then open incision will find its legitimate place in surgery.

What are the advantages of the operation? 1, Cutting parts as they offer resistance in their respective order

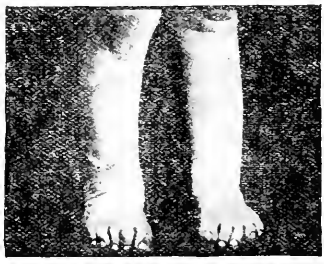

Fig. 12.

prevents the operator from needlessly cutting tissue not deformed by contraction; 2, after the subcutaneous tenotomy of the tendo-Achillis the tibialis posticus tendon is easily cut, through an open wound, near its attachment to the scaphoid, ligamentous contraction at this point can also be then divided; 3, through this open wound contracted parts can be extensively cut without wounding the plantar arteries or nerves; 4, after all contracted

Fig. 13.

soft parts have been divided, including the skin (which, by the way, in this class of cases is always short, and from its intimate connection with the plantar fascia would defeat the object of the operation), the operator can ascertain the amount of deformity of the bones, and if any considerable amount exists it can be easily remedied with a chisel; 5, it restores the foot to its natural length by lengthening the shortened side; 6, it makes the surgeon

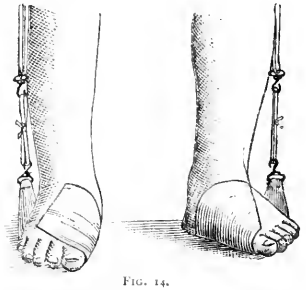

Fig. 14.

master of the situation; he advances step by step in a proper order, and need not stop or retreat until the deformity is overcome, beginning with manipulation and subcutaneous tenotomy, and ending with osteotomy, if necessary.

I desire to say that osteotomy should not be resorted to as a primary operation, and not until after the contracted soft parts have been lengthened, for the reason that in primary osteotomy the bones of the foot must be amount of deformity in the bones until after he has relieved all the contracted soft parts, and a slight deformity in the bones had better be left than to resort to an extensive osteotomy.

The word "Perfect" used in the above report signifies a straight and useful foot, either toeing straight ahead or out, with normal functions fairly well preserved. The words "Good" and "Fair" signify intoeing of foot, with congenital defect either in the ankle-joint, tibia, or muscles, but useful feet, walking on plantar surface.

shortened just in proportion to the amount of shortening of the soft parts; and in a vast majority of cases of this form of intractable club-foot it will be found unnecessary after the steps which I have detailed have been taken. And certainly no operator can determine the

To summarize: In 93 cases there were 161 operations performed, the average age being six and a half years, the average time of healing of the primary wound was four weeks, there were 117 cases of blood-clot organization, 4 catgut, and 19 failures in 140 cases.

The duration of after-treatment was ten months. On the fourth month after operating the feet were all straight. Out of 140 cases traced after one year, 10 cases were found relapsed, or partially so, from neglect. I will say that relapses, when they occur, take place during the first year after the operation as a general rule.

There were performed 10 linear osteotomies. 5 linear osteotomies with cuneiform resection from os calcis or cuboid, and 2 linear and cuneiform osteotomies, together with removal of both cuboid and scaphoid bones, making in all 17 osteotomies.

These results vary but little from those of Dr. Kaptyn's, of Abcande, Amsterdam, who has kindly furnished me with the statistics of 42 operations in 36 cases from Holland. In this series 34 were very good, 1 materially improved, fair results in 6, and 1 still under treatment. In other words, good results were obtained in 36 feet, with useful feet in all the others, except 1, which is unknown.

I find in looking over the literature on the subject, the following reported cases: Hoffe, 6; Schede, 20; Nunchen, 13; Oliva, 6; Postempski, 1; Schreiber, 11; Lowenstein, 2; Jones, 10; Roman, 3; Giordane, 1; Motta, 7; Volkman, 21; Kirmison and Rochard, 7; Ambrose, 1; Phillipson, 3; Levy, 9; Kaptyn, 42; Post, 2; Hamburg Medical, 1884, 12; Hingston, 4; the writer, 161—making in all 342. (This includes the cases of Professor Tilanus, Professor Korteweg, Dr. Konwer, Professor Sterson, Vander Hoeren, Dr. Dunnewold.)

All the cases at the time of reporting upon them were good results. In no case did I find a sensitive scar, a flat foot, or paralysis following the operation. No considerable atrophy of the muscles of the limb followed the operation in any case; the motion of the toes was preserved in nearly all the cases. In those with loss of flexion of toes, locomotion seemed to be as perfect.

One hundred and forty-four cases had already run the gauntlet of tenotomy and instrumental treatment, with a relapse in each case.

A CASE OF INFLAMMATORY RHEUMATISM—PURPURA—UNUSUAL TOLERANCE OF SODIUM SALICYLATE.[1]

By W. H. KATZENBACH, M.D.,

NEW YORK.

Mr. H——, twenty years of age, went to bed on the night of May 10th in good health. At three o'clock the following morning he was awakened by a chill and sore throat. Before daylight he had burning fever. He was visited by the writer at 10 A.M. At this time his temperature was 103.3 F., respiration 30, and pulse 120. He complained of intense headache, and pain in nearly every large joint. The fauces and pharynx were red and swollen, but the tonsils were not enlarged. Deglutition was difficult and painful. He was given acetanilid, gr. v., every three hours. At 4 P.M. the temperature was 100.3° F., pulse 114; at 9.30 P.M. temperature 99.6° F., pulse 100. He was then ordered salol, gr. x., every three hours.

May 12th all the large joints were involved; also the metacarpo-phalangeal, and the surfaces of the latter were of a bright-red color. Purpuric spots of small size (from a pin-head to a large pea) were thickly scattered over the arms, legs, and trunk. The most painful joints were the right knee and great toe, and the left ankle, and these, though not much swollen, were quite red; morphine became necessary. On the morning of this day the temperature was 100° F., and pulse 100. Salol was continued until noon of May 14th. The throat had been relieved, but the joints continued very painful. On this account salol was discontinued and sodium salicylate was ordered in doses of twenty grains every two hours, until rheumatism should be relieved, or the physiological action of the drug obtained; the dose to be increased if necessary. It was administered in capsules. May 14th he took 105 grains; May 15th, 240 grains; May 16th, 235 grains; May 17th 235 grains; May 18th, 165 grains; May 19th, 160 grains; May 20th, 140 grains; May 21st, 160 grains; May 22d, 140 grains; May 23d, 100 grains; May 24th, 30 grains.

During eleven days he took 1,710 grains, or more than three ounces, an average daily dose of 155⅓ grains. All the joints except the left elbow and shoulder yielded to this treatment, and the purpura rapidly disappeared. At no time was the stomach disturbed. The skin acted freely. Tinnitus and deafness were produced, but not to an annoying extent. Pain and stiffness persisting in the left shoulder and elbow, dithio-salicylate of soda was given in doses of gr. iij. every three or four hours, with good result, for several days. During convalescence, which progressed very favorably, the heart-sounds were weak, and a systolic murmur was heard over the body and apex of the organ. In June he went to the St. Lawrence.

On his return to the city in September, he had entirely regained flesh and strength. The heart-murmur had disappeared.

[1] Reported to the New York Clinical Society, October 24, 1890.

PARALDEHYDE ADDICTION.

By B. MATTISON, M.D.,

BROOKLYN, N. Y.

Dr. Hoyt's recent paper in the Record, on Paraldehyde, is of interest and value, but he is mistaken in saying "its continued administration has no tendency to produce a habit."

Paraldehydism is a *fact*—though rare. In Pepper's "System of Medicine," vol. v., p. 666, a well-marked case is cited; and, as this work may not be at command, an extract is given.

Patient, a young married woman, who had recovered from chloralism, took paraldehyde for insomnia, with success. "Notwithstanding its disagreeable and persistent ethereal odor, and the precautions taken by the physician, this lady managed to secure it, at first in small quantities, afterward in half-pound bottles, from a wholesale druggist, and took it in enormous amounts, with the result of producing aggravated nervous and psychical disturbances, corresponding to those produced by chloral, but without the disturbances of nutrition attendant upon the abuse of the latter drug. The patient remained well nourished, retained her appetite and digestion, and was free from disorders of the skin and the intense neuralgia which had been present during both periods of chloral abuse. She suffered, however, from a persistent binding headache, disturbances of accommodation, phosphène, and brow pains. Under the influence of moderate doses, she was enabled to take part in social life with some of her old interest and vivacity. The brief intervals of abstinence which occasionally occurred were characterized by distressing indifference to her friends and surroundings, and by apathy and depression. At frequently recurring intervals the indulgence in excessive doses, constituting actual paraldehyde debauches, was followed at first by maniacal excitement of some hours' duration, later by profound comatose sleep lasting from one to three days. Upon the complete withdrawal of the drug this patient manifested the symptons produced by complete abstinence in the confirmed morphine habit.—yawning, anorexia, epigastric pains, vomiting, diarrhœa, absolute sleeplessness extending over several days, heart failure, collapse, colliquative sweating, and finally well-characterized delirium tremens. At the end of a week, under the influence of repeated small doses of codeine, sleep was secured, and within a month convalescence was complete."

Some time ago, the writer was asked to visit a medical man in the interior of the State, who had become addicted to paraldehyde. The case proved fatal, but whether from the drug or other disease, cannot now be stated.

In the early days of chloral, the same claim to non-ensnaring power was made, but that was soon proved baseless; and in a paper by the writer, on "Chloral Inebriety," read before the Kings County Medical Society, in 1879, several well-marked cases of chloralism were noted. Happily they are becoming more and more rare, due to later soporifics, but doubtless we shall see the same pernicious result from rival hypnotic claimants. Already, sulphonalism is here, and chloralamid—the newest and best—will probably not be long in joining the procession.

Addresses made before the New York Academy of Medicine.

THE ADDRESS OF THE PRESIDENT,[1]

ALFRED L. LOOMIS, M.D.

FELLOWS OF THE NEW YORK ACADEMY OF MEDICINE, LADIES, AND GENTLEMEN: I count myself most fortunate that it is my privilege to speak to you words of welcome in our new home. The only language which my heart prompts me to utter to-night is the language of congratulation, congratulations for the past, the present, and the future of our Academy.

Forty-four years ago representative men in different departments of medicine, actuated by a spirit of devotion to a high scientific purpose, founded this Academy. Interwoven with its early history are the names of John Stearns and John N. Francis, Alexander Stevens and Alexander Hosack, John W. Draper and Joseph M. Smith, Valentine Mott and Francis Delafield, and a long list of others whose name and medical achievements made honorable the medical profession of their day.

With such founders the membership of the Academy soon included most of the active medical workers in the city, and became the strongest and one of the most influential medical organizations in the State. From year to year it has grown in professional esteem and public confidence, and its advancing history has been stamped by the life and labors of such noble ones as Willard Parker, Alfred C. Post, James Anderson, Alonzo Clark, Edmond R. Peaslee, Austin Flint, William H. Van Buren, James R. Wood, Cornelius R. Agnew, and a host of less prominent, but noble, self-sacrificing spirits around whose memories we delight to linger.

Time will not permit me at this hour to even mention the many important papers that have been read and discussed, and the large amount of original work which has become a part of the scientific history of this Academy. As one reviews the scientific work of those earlier years, he congratulates himself that he is a fellow of such a fellowship. An organization which has given so much to the profession as ours has a past for each one of us to be proud of, and I may well congratulate you this evening on the past of the New York Academy of Medicine. We step to-night into a present full of promise.

"In my inaugural address, less than two years ago, I stated that in order that our Academy might become the centre of the scientific activities of the entire profession of this city it must have a suitable home, a building that should furnish accommodations for a large and well-selected library, with reading-rooms and commodious meeting-rooms for all our medical societies. Such a building is ours to-night, more elegant, commodious, and better suited to our wants and work than the most sanguine could have hoped for two years ago.

With a library capacity for two hundred thousand volumes, and a well selected library of fifty thousand volumes, supplemented by the largest and best collection of journals to be found in this country, we may rightfully claim that we are in some degree meeting the highest requirements of scientific medicine. The influence which such a library will have, not only on the intellectual status and culture of the profession, but upon its moral tone, cannot be estimated, for there is an atmosphere about a large and well selected library which does not favor the growth of a mean, money-calculating spirit; it conduces to broadness, tolerance, and a love of the higher and nobler attributes of man.

Our membership has reached nearly seven hundred, and includes most of the active workers in our profession in this city, and many in the State. Every specialty in medicine is represented by those who have become distinguished in their chosen lines of work. There are now established and well-organized sections in all the special departments of medicine and surgery, so that each fellow may find a place with congenial workers for making public the results of his own observations and experiments, under the sifting criticism of experts, and thus learn what may have been done by others, in the way of support, or in opposition to his own work. The combined scientific labors of our general meetings and sections is to a large degree leading and guiding the medical thought and research not only of our own country, but its influence is being felt in the medical councils of Europe.

We are also exerting an increasing influence on public thought and action. We are becoming a power in this city and State which is being more and more felt in the legislative and economic work of our commonwealth. The public health and safety of our citizens is being more and more committed to our hands, with the conviction that, by wise councils and practical methods, we shall protect it from the ravages of disease by an ever-broadening and more perfect sanitary science.

Our fellow-citizens, in response to our appeals made to them during the past two years, have shown by their sympathy and liberal donations that they are recognizing more and more the importance of our work and its influence upon the general weal. Let us act wisely, energetically, and unitedly, and we may be assured that in the near future we shall be able to turn more largely the influence of the accumulated wealth of this great metropolis into channels for the support and encouragement of scientific medicine. Our profession was never so full of promise as at the present—never before were there so many strong men in its front ranks as now, never were there so many cultured and brilliant minds entering it as to day. If this great and daily increasing power can be centralized, as is possible, within these walls, its influence on the social, domestic, business, and religious life of our city cannot be estimated; already the better minds in all departments of science are turning to us for help and inspiration. There is no longer a strife of sects or creed, but a struggle for the supremacy of intellectual power and broad culture over weakness and charlatanism. There is no place in the broad field of scientific medical inquiry for the would-be medical man who talks of the potential power of infinitesimal abstractions, and the so-called scholastic illusions. We are living in, and are part of an age of facts, not fancies, work, not theories. This epoch in medicine is indeed more brilliant and eventful than any which has preceded it, and the prospectus grows constantly more encouraging and richer in possibilities. The effect of the many enthusiastic workers who to-day are struggling for truth in medicine must produce a general advance, notwithstanding as Dr. John W. Draper once said, "there has been through all the ages constantly hovering about honest workers in our science a host of impostors and quacks, who will continue to thrive so long as there are weak-minded and shallow men to be deluded and vain and silly women to believe."

I congratulate you, then, that with the most advanced workers in every department of scientific medicine gathered in our fellowship, we meet to-night about our own hearth-stone in full possession of all those faculties which are needed to render our work most efficient and stimulate us to still higher achievement in the future, so that

[1] Made November 20, 1890, see p. 613.

the work done in these halls shall have a forming and crystallizing power on the medical literature of our whole country.

The days of doubt and anxiety are past, success has ceased to be a question, the auspicious present marks the beginning of a new and broader career for our Academy. It is here, in the centre of this great city, to do its part in stimulating its intellectual and moral forces. With increasing opportunities come deeper obligations. Our future must not be gauged by past successes or present advances. We are under obligations to the past, but under bonds to the future. As we in turn pass this trust to our successors, to those who in the future are to be the exponents of the lofty mission to which this building is dedicated this evening, it must not have suffered in our hands, but have grown and broadened under the impulse of true enthusiasm and faithful work. Yesterday we read the history of the past, to-day we make history for the future, and whether he will or no, every fellow in our number must leave his mark, be it little or much, in the records of this Academy. Let us be inspired, then, with the thought that our fellowship shall become a power in raising our profession to the high place which the future shall assign to it, centralizing its influence, and elevating it socially and intellectually to a position which was not hoped for in the past, or attained to in the present.

Our future must be, and will be, interwoven with the many and rapid transformations that are to take place in every department of science, and our relations must become more and more intimate with the great public, who are fast realizing that the first mission of our labors is the prevention of disease. The career of the physician of the future will be nobler and pleasanter, because he will have less of ignorance and prejudice to combat, but he will require a higher culture than his representative of to-day. Here in this library and in these halls, both the medical profession and the philanthropist will find that inspiration which shall give birth to a greater devotion to the alleviation of human suffering and a better realization of our duty in the elevation of the masses to a higher civilization. We must never look backward, but always forward. Provided with the machinery of wisdom we have inherited, but not wise in our own conceits, let us make this building the great workshop, where the fires of scientific enthusiasm and persistent labor shall smelt from out the ores of our daily experience the pure metal of truth, that, cast in the moulds of patient thought and polished by the sharp emery of keen and kindly criticism, may some day furnish to generations yet unborn armor and weapons with which they will advance victorious over all the forces of death; save three score years and ten.

So shall the congratulations which we utter to-night re-echo from these walls when other voices recall this day. Join with me, then, in thanksgiving to the Great Physician for what has been accomplished, and in this invocation, that these walls may not crumble or cease to shelter faithful, earnest, Christian men, until suffering humanity is free from its bondage to lust and excess, and is victorious in its struggle against the invisible arrows of disease.

THE NEW YORK ACADEMY OF MEDICINE.[1]

BY E. L. KEYES, M.D.,

NEW YORK.

MR. PRESIDENT, FELLOWS OF THE ACADEMY, GENTLEMEN, AND LADIES: If there are sermons in stones—then an address has already been delivered to you to night on entering these walls, in a strain of greater dignity than any to which I may aspire. The fact of the existence of this building at all in the graceful form in which you see it, devoted, as it is to be, to philanthropic and humanitarian ends—this in itself is a whole volume, a canticle of praise to the energy of its promoters, and a pean of gratitude to the liberality of those whose material bounty has made its erection a possibility.

Those of us who are to possess this well-equipped arena for scientific effort, this nucleus from which shall radiate ever broadening lines of medical thought, have lived to see a good day, and to enter the promised land toward which our earnest expectancy has led us through many a long hour and weary year; and in contemplation of the work accomplished, in that grateful lassitude which accompanies the consummation of a successful effort, we might perhaps with better grace muffle our ineffective voices and allow the stones to discourse to you in the eloquence of their majestic silence.

Yet this may not be. Some articulate words are called for, and if I, who have been honored by being made the mouth-piece of my fellow academicians, can, as an impersonality, render to you for them any words in harmony with the occasion, the accomplishment of the pleasant duty will be its fitting reward.

An academy is an institution sanctioned by illustrious precedent in that group of devoted followers who, in the groves of the suburb of Athens bearing this name, in the year 348 before Christ, clustered around Plato as he "taught the truth;" and to teach the truth after investigation has been the proper function of the academy ever since that day. The various institutions of learning which in different scientific fields have borne this name have made for themselves everlasting renown and have established a criterion by which, if our little body of earnest workers is to be judged, it behooves us to spare no effort that our results may be deemed worthy to be enrolled upon the same scroll of honor.

The age in which we live is distinguished notably along three prominent lines: by material progress, by the broad dispensation of rational charity, and by the far-reaching effectiveness of scientific study in its practical application to the needs of mankind.

This building in which we are assembled represents a crystallization of the essence of all these lines. The material progress is represented by the graceful outlines of the building and its commodious internal structure, which the architect has ably conceived and the workmen faithfully executed. The very existence of the building is the acme of a broad charity, since it stands for the accumulation of many hard-earned dollars; that this institution may live and become effective, not solely for those who make immediate use of it, but that the fruit of their labors may spread abroad through the land for the benefit alike of all who are in need; and it stands for science, for it is the rostrum from which science speaks; it is the arena in which science contends; it is the soil in which are implanted the roots of that tree of medical knowledge, in the branches of which the investigator may find the bud, the flower, the ripening fruit of past experience; it is the fountain from which shall emanate rivers of refreshing sweetness to cool and succor the parched sufferer along the dusty highways of disease.

And what to say of the academic body itself, of which this edifice is the outward and visible sign? Conceived, as its historians have often narrated, conceived in the spirit of good-fellowship and brotherly kindness on the evening of November 18, 1846, at a dinner of the Society for the Relief of Widows and Orphans of Medical Men, it took shape December 12, 1846, with the sanction of about two hundred and fifty physicians, under the immediate direction of Alexander H. Stevens, assisted by Parker, Watson, Mott, Isaac Wood, Smith, and others, was born on January 6, 1847, and baptized by legislative enactment of incorporation June 23, 1851.

The motive for its formation was stated by its founders to be the recognition of a "lack of harmony and concentration of effort for scientific purposes in the profession," and a desire to elevate a barrier against quackery, which, at that time, it appears, had reared a more formidable front than before, or, possibly, since that day.

[1] Being an address delivered on the occasion of the opening of the building, November 20, 1890.

At its birth its future functions were defined to be: 1, The cultivation of the science of medicine; 2, the advancement of the character and honor of the profession; 3, the elevation of the standard of medical education; 4, the promotion of the public health.

The Academy is therefore now in its fifth decade. It has lived through its babyhood and period of riotous youth, homeless at first, wandering about seeking shelter, and having no roof to call its own, until well along in its twenty-seventh year, when, on December 24, 1874, it secured, largely through the energy of Dr. S. S. Purple, a permanent abiding-place at 12 West Thirty-first Street.

There might almost be said of the Academy what has been tersely written of the life of man, dividing it into decades:

"At ten, a child,
At twenty, wild,
At thirty, sound—if ever—
At forty, wise,
At fifty, rich,
At sixty, good—or never."

except that the Academy has been from the beginning good, a quality which may not be affirmed with equal confidence of all men.

For surely at ten the Academy was a child, and a wanderer in the streets; at twenty we may be pardoned for declining to inquire into her follies; at thirty she was certainly sound—indeed there never has been a question of the health of the organization; at forty who shall deny that she was wise, for it was in the early forties that the necessity for expansion was felt, and that spirit generated which has culminated in this our forty-fourth year in the completion of this modern home, in which the treasures of our library will be adequately protected from fire, and wherein ample provision has been made for the convenience of present work and future expansion. And in signalling this triumph of the Academy's fifth decade, it is impossible not to pause and pay tribute to our President, Dr. Loomis, whose energy, zeal, and ability have contributed so largely toward the accomplishment of the result.

It is hardly necessary to carry the simile further. At fifty the Academy cannot fail to be rich. She is rich now in the love of her children, in the respect in which she is held by the community at large; she is rich in her library, and in the accummulation of good work by her members. This is the material wealth of a scientific body, and of this she has already a fund and a steadily increasing store.

At sixty the Academy becomes immortal, and will remain until the consummation of time a pillar of beauty and strength, an integral part in the grand temple of science which is being reared by zealous and loving hands throughout the length and breadth of the entire earth.

And how has the Academy fulfilled the aspirations of her founders? Surely the end is not yet, and more remains to do, but in the four directions which were defined at her origin as her special lines of effort, her advance has certainly been satisfactory. The science of medicine has been cultivated; the division of labor into section work has brought together spirits scientifically akin, and the quality of the material presented to, and digested by, these sections is of a high order and of steadily increasing excellence. The character and honor of the profession have been sustained; struggling factions have been dominated by wise counsels, and threatened rupture averted by the exhibition of a broad spirit of professional charity, which has helped to steady and elevate the quality of the professional gentleman, without, as well as within, the academic circle.

The weight of the Academy has always been thrown into the scale to help to raise the standard of medical education, both by the personal effort of the fellows, many of whom have occupied high positions as instructors in the various institutions of learning, and in efforts to help shape legislation toward the accomplishment of the same result upon a large scale.

That the promotion of the public health has been an object of academic solicitude is witnessed by the present existence of our efficient City Board of Health, which was conceived and formed in the bosom of this Academy in the interest of the citizens of New York.

The workers in the academic field have not been very numerous. The present roll, the largest ever possessed, numbers seven hundred; but in that number may be found the names of nearly every living physician of recognized eminence in the city and immediate neighborhood; and it is difficult to mention any of the illustrious dead of our profession whose names will not be found written upon the roll of the Academy, as well as imprinted upon the memory and in the hearts of those who loved them for their kindliness during life. How shall I mention any without slighting more: Francis, Mott, Stevens, Parker, with his genial smile; Watson, Post, Peaslee, Flint, the good physician, the crystallization of benevolence; Rogers, Bumstead, Buck, Wood, the man of action; Delafield, Clark, Dalton, Anderson, Agnew, the Christian gentleman; Hamilton, Sims, Van Buren, the man of judgment, the man of dignity, a very man, a prince among his peers; but why prolong the list? the good men have been ours, the good men are ours, and their work, the best of it, is fostered by this Academy and turned to good account.

And yet the high success of the few is not the measure of the usefulness of the Academy. These illustrious ones would have glittered without the Academy. Their lustre is shed back and illumines the whole body in which they mingled, and multiplies there for the good of the community at large.

We in our scientific struggle and effort are much like children. The vastness of the field belittles our personality. The pretentious few who arrogate to themselves a personal superiority are more than liable to be left behind by the patient seeker after truth whose path is lightened by the glowing rays of human kindness. Children we are indeed!

"We go forth like children in the morning,
Scattering, to spend the summer hours;
One, his brow with laurel wreaths adorning,
One to saunter 'mid a grove of flowers;

"One to lose his way and wander, straying,
'Till the twilight, frightened and alone;
One, it may be, wearied with his playing,
Wending home his footsteps e'er the noon.

"But, whatever fate to us is given,
All, when day is done, again shall meet,
And at nightfall, 'neath the stars of heaven,
Shall be gathered at our Father's feet."

To obtain an idea of the relative standing of this Academy, we must compare it with other analogous institutions. The Imperial Academy of Science in Vienna, and that of France, are scientific, not medical, bodies. There is a Royal Academy of Medicine in Belgium, one in Italy, one in Ireland; there is an American Academy of Medicine, one in Kansas, and one in Detroit, but the moderate scope and importance of these various academies relieve them from comparison. Germany is justly proud of her two distinguished associations in Berlin—the Medical Society under the presidency of Virchow, and the Society for Internal Medicine under the leadership of Lyden. Illustrious names glitter in each of these constellations, but neither has a building of its own yet, although the Medical Society is now erecting one in company with the Berlin Surgical Society. The library of the Medical Society is about two thirds the size of our library, while that of the Society for Internal Medicine is insignificant. The great Austrian medical body, the Royal Imperial Society of Physicians, in Vienna, justly renowned for the brilliancy of its work and the standing of its members, has no building of its own, and a library of some-

thing over eleven thousand volumes, not one-third the size of ours, although the society is ten years older. Of the Surgical Society of Paris, and other foreign medical associations, it may be said that, whatever their distinction, they are not sufficiently analogous bodies to be fairly compared with our Academy.

Two foreign institutions, however, fulfil the conditions: The Academy of Medicine in Paris, and the Royal Medical and Chirurgical Society of London, upon the general plan of which our organization was outlined.

As between these two and ourselves, at this date, in evidences of material prosperity at least, our Academy holds its own. As to the scientific standing of the members, I shall not draw comparisons. It is enough to say that each of them contains the flower of the medical science and art in the districts in which they are respectively situated. In this country there is no other Academy (except the relatively unimportant ones I have mentioned), although there are many notable Medical and Surgical Societies; but the extent of our land, and the wide-spread distribution of its talent, make it probable that others will shortly arise.

Comparing, then, some of the main points in the three that I have selected, I may say that each has a building of its own—that of the French Academy being a temporary one. They have the funds, and propose constructing a suitable home in the near future.

Royal Medical Chirurgical Society, London, founded 1805, membership seven hundred, seating capacity of largest hall three hundred, area of hall 40 by 50 feet, foundation area of building 50 by 200 feet.

Academy of Medicine, Paris, founded 1820, membership one hundred and ten, seating capacity of largest hall ninety-two, area of hall small, foundation area of building small.

Academy of Medicine, New York, founded 1847, membership seven hundred, seating capacity of largest hall three hundred and fifty, plus extra opened-up space two hundred and fifty, equals six hundred; area of hall 42 by 57 feet, and two extra smaller rooms that may be opened into it, foundation area of building 75 by 100 feet.

All have libraries, but on this point we may seek a wider field for comparison. Our library, which is, I believe, the youngest on the list, and which always gratefully recalls the names of its chief munificent donors, Purple, Dubois, Bumstead, Stone, Jacoby, and many others whom time forbids me to detail, was founded by donations in 1877, never bought a book until 1879, eleven years ago, yet now, safely housed in a fire-proof home, we are proud in possessing the third place numerically among the medical libraries of America, and the fourth place, as far as I can learn, among the purely medical libraries of the world. In this country the library of the Surgeon-General's office in Washington, founded in 1865, is the largest, that of the College of Physicians in Philadelphia, more than one hundred years old, the second.

Comparative Table of Medical Libraries.

Name of Library.	Date.	Volumes.	Journals.	Current Journals.	Pamphlets.
Academy of Medicine, Paris.	1820	130,000	18,000	300	
Surgeon-General's Office, Washington	1865	97,886	33,173	over 700	144,887
College of Physicians, Philadelphia	1789	45,000	.....	400	
Academy of Medicine, New York	1847	10,000	.....	400	
Medical and Chirurgical Society, London	1805	36,000	.....	150	
Medical Society, Berlin	1839	about 30,000			
Royal College of Surgeons, Dublin	....	about 25,000			
Medical Library Association, Boston	....	19,365	....	381	19,100
New York Hospital Library, New York	....	18,386	....	109	No record kept.
Royal Imperial Society of Physicians, Vienna	....	11,069	....	132	
Aberdeen Medical Society, Scotland	....	6,000			

So stands our Academy, and such she is when compared with other analogous institutions in other parts of the world. Considering her age she need not be ashamed. To fulfil her destiny and consummate her function requires only a continuance of the zeal which has attended her development from the first, and a common impulse among her members to work for work's sake.

Here in this hall, now radiant with the gracious smiles of approving friends, must be fought out many a desperate scientific battle. Clad in the armor of scientific method and wielding the sword of personal experiment and investigation, contending individuals and contending factions shall battle for the supremacy of their ideas, until these walls shall resound with the din of conflict; and from the blows given and taken with such weapons upon such honest armor there shall scintillate and radiate sparks and flashes of truth, living fire, to be added to, and heaped upon, the burning flame that glows forever upon that common altar of Science at which we all worship, a flame to act as a beacon of safety upon the hilltop to encourage those for whom the battle is fought—the patient, suffering victims of disease—and a flame which, within this academic body, shall serve as a cloud of smoke by day and a pillar of fire by night to guide and guard the honest investigator in his never-ending endeavor to teach the Truth.

OUR LIBRARY.[1]

By A. JACOBI, M.D.,
NEW YORK.

Mr. President, Ladies, and Gentlemen: A circular, published by a special committee of this Academy in January, 1888, contained the statement that the New York Academy of Medicine was an incorporated institution, then more than forty years old; that its object was the cultivation of medical science and art; and that this aim was, among other means, reached by maintaining reading-rooms which furnished nearly all the medical journals of the world, and by collecting a library which was—and is to-day—free to the fellows of the Academy, to the whole medical profession indiscriminately, and to the public at large. Our library was steadily increasing, the capacity of its shelves strained to the utmost, the building not fire-proof, and our accumulated treasures were in constant danger. For these reasons we appealed to both the profession and the public for aid in procuring for our meetings and our books a fire-proof building large enough to accommodate two hundred and fifty thousand volumes, spacious enough to afford quarters to all the scientific societies of the city, stately enough to worthily represent the medical profession of the metropolis, and able to testify both to the unity and earnestness of that profession and the sympathy of the city, which at the same time is the largest in size and the greatest commercial power of the continent.

This library of the Academy of Medicine had a slow but steady growth. Thirty-three years ago, when I was admitted to membership, in the presence of the great and good men who then were the guiding stars of the profession, Alexander Stephens, Valentine Mott, Horace Greer, Gurdon Buck, Edward Peaslee, Edward Delafield, John Francis, John Watson, Ernst Krackowizer, there was no library at all, not even a medical reading room in the city. It took many years before the Journal Association was organized, which furnished, in a room fitted up for the purpose in 64 Madison Avenue, the current medical journals. Other years elapsed, until an amalgamation of the Journal Association and the Academy of Medicine, then in 12 West Thirty-first Street, was brought about. The accumulation of the annual volumes, and a valuable collection of American journals and other books presented by two fellows, were the first stock of the library. The journals were paid for by an appropriation of the Academy, which being small in the beginning, for many years

[1] Being an address delivered before the New York Academy of Medicine on the occasion of the opening, November 20, 1890.

amounted to from three to four thousand dollars annually. More could not be spared. Thus it was that we could not purchase new books. Occasionally a sum was raised by voluntary contributions for the purpose of buying the collection of a deceased member, certain publishers would present us with their publications, authors donate copies of their writings, fellows and others give old and new books, and men interested in special branches of literature furnish a shelfful of special works. The largest and most valuable addition of the kind was bequeathed to us by the great specialist, Dr. Freeman J. Bumstead. That was our library. Thus it grew slowly, but steadily. In the course of years our stock of journals became more and more valuable, but what we wanted was a regular supply of new books, for which we had no funds at all.

On October 2, 1889, when I had the honor of addressing you at the laying of the corner-stone of this edifice, I could refer to the fact that at last we had, for the purchase of new books, a special library fund of ten thousand dollars, half of which was a memorial gift. For the same purpose and in the same spirit the widow of a deceased fellow and vice-president has since presented another special fund of ten thousand dollars, so that one-fifth of the sum required for the perpetual endowment of the library is now secured. We are thus approaching the time when New York City will possess a medical library fully adapted to meet its ends. What are they? A large library, besides being the proof of existing culture and accumulated intellectual labor, fulfils its destiny by giving information. Here the medical man with scanty means will find his text-books and monographs to aid him in unravelling the obscurities of a difficult case on hand. He with an ample library of his own will come here to consult rare books, old journals, expensive works. Here all the journals of the world may be consulted from day to day; here those who are engaged in literary pursuits find their historical records. But what a library is most successful in is the inculcation in a great many of the habits of study and research. In that result the public is very much interested. Its safety and dignity requires cultured and erudite physicians.

In the same degree that the ethical and intellectual standard of society is raised the community will demand a higher standard of education and culture on the part of its liberal professions, among them the medical. A profession is called liberal in this, that it is generous, charitable, and high minded; in this, that it liberates its members from ignorance and mental and moral hebetude. But in reality the medical profession of the country was mostly liberal in this, that it admitted to its ranks uneducated persons of all colors, sexes, ages, and previous conditions of servitude and illiteracy. Instead of being a truly liberal profession, it has merely been too liberal. In this tendency it has been encouraged, or rather this inferior standard has been forced upon the medical profession, by the public. He who requires manners in his corn-cutter, and demands gentleness in his tailor, would often not object to selecting for his family physician and public hygienist a medical adviser with the orthography of a village school, the touch of the corner grocer, and the mental level of a soap pedler.

From this depth the profession has risen spontaneously by study and its indigenous moral development Not all of you know, however, to what extent you are under obligation to the medical profession. Fifteen years of incessant agitation were required to finally pass the bill for the establishment of a State Board of Medical Examiners. If in future you will be protected against practitioners who have nothing to show besides their diploma, granted by a college—no matter of high or low standing—if the license to practise on you, your parents and children will be made dependent on a second examination, you owe that blessing to the exertions of the medical profession. You might have made the result more striking. If the public had understood its interest you would have worked with us, in behalf of making the State Board one, and not three.

Another achievement of the profession which concerns you as much as it does us, is the final passing of the bill requiring some degree of general education on the part of every medical student who expects to obtain his medical diploma. Thus a step is made in the direction of rendering the profession more liberal, more cultured, more effective, more fit to take charge of the most sacred offices that can fall to the lot of men. For the holiest and greatest of the objects of human study and care is man. That is so much a part of the creed of the medical profession that you can imagine the painful and contemptuous surprise at our learning that a medical man, in a public position, but fortunately not one of us, worked all winter to have the law repealed.

Fortunately not one of us. For from its very first days this Academy of Medicine had the elevation of the standard of medical education and culture inscribed on its banner. That object has become such a settled axiom in the mind of every fellow, that, years ago, it was no longer considered necessary to retain it in just as many words among the written laws. In this tendency you can sustain the efforts of the profession. Insist upon this, that your physician be a gentleman and a scientist, and do something for that purpose yourself. For the State does not contribute to that end. The State is only society organized for certain purposes of co-operation and protection. But medical education, though ever so indispensable for the pursuit of health and happiness, and the training of erudite and liberal physicians, has not been recognized among them. But you who do not say to the hungry, the cold, and the naked, "Be ye fed, be ye warmed, be ye clothed," without helping them to food, fire, or clothing, must not expect a profession that always works in the private and public interest of yourself and all those dear to you and yours to be at once learned, erudite, and wise, and refuse aid in its efforts to perfect itself and benefit the commonwealth, aid by pecuniary support, by your social influence, and also some occasional gentle political pressure on our representatives in Albany.

Our greatest drawback has long been that we had no large class of learned medical men, such as study for study's sake, irrespective of pecuniary gain. Our profession has always consisted of practitioners. The necessities of life have acted upon the medical fraternity as on the community at large, which knew but exceptionally of art, of music, of philosophical refinement as long as the country was still wrestling with the difficulties of the soil, the insufficiency of commerce, and the hamperings of poverty. Thus the immense majority of the medical men of the country gloried in being practical, and that only. That there were architects who never laid a brick, mathematicians who never triangled a mountain, astronomers who never sailed a ship; that no cathedral, no coast survey, no ocean travel could exist without them, that indeed there is no rational practice without an underlying theory was not considered. The very strongholds of medicine, histology, physiology, the fields of experimental labor and microscopical research, all those branches which you cannot immediately exchange for cash, have been neglected among us until lately. Like special laboratories, it is but a short time since great medical libraries have sprung up in Washington, Philadelphia, Boston, and New York. The sooner we admit that we have been far behind Europe in that respect, the better for our scientific future. Indeed, the intellectual maturity of a nation can best be measured by the amount of its original and unpaid research. Europe knows that thoroughly. The intellectual atmosphere of Paris depends greatly on its universities. The universities of Germany, with their independent workers and thinkers, have always been the pride of the nation, even in the distress of national poverty and political humiliation. In all of them the principal means of information, through centuries, have been their large libraries. And it will be our library round

which the scientific interests of the profession will largely centre; but not of the profession only, for the Academy, as it opens its doors to whosoever will attend, without regard to membership, has always held that in order to increase the number of its beneficiaries it must make its library free. This is so well understood and so highly appreciated that the city has released the taxes on its building. A medical library contains of necessity many works and journals of interest to professional men besides medical. The lawyer and physician have many studies in common. There are in the city two societies for the special study of forensic medicine and medical jurisprudence, both of which can be better studied in a medical than a legal collection. Nor is a medical library, such as we have and mean to increase, a forbidden fruit to the intelligent, well-informed non-professional man or woman. Fortunately there are a great many good popular works, besides those compiled for an ephemeral market, which treat of physiology, hygiene, statistics, and other topics of universal interest.

Therefore we hold that the profession has a right to look to the public for appreciation and aid. We are not situated as they are in Europe, where educational institutes —as they are controlled—are also supported by the government. For the democratic spirit of our social and political institutions is opposed to centralization of that kind, and the generosity of the citizens has often been appealed to, and hardly ever in vain. There was a time when the church, centralizing all information, beneficence, and social and political influence, was the only legatee of the rich and benevolent. Now there are a hundred opportunities for liberal outlay. To select the proper ones is an art. I suppose it is a great achievement, which only a few select ones can attain, to make money; but it is a greater art to spend it both generously and profitably in the interest of science and charity. The greatest of all charities, however, is to benefit mankind by levelling the road of science. It is not millions we want. A hundred thousand dollars will clear this temple of sciences from debt, and swell our library fund to a sufficient sum, the interest of which will forever supply us with everything medical and scientific that will appear in any country. Well-to-do ladies and gentleman will, I hope, not leave this building without making up their minds to contribute their share to the extinction of a debt which the community owes to the profession and to itself through improved educational facilities. "Let your light so shine before men, that they may see your good works."

In conclusion, my friends of the profession may permit an additional word or two on the subject of the library, which is so dear to all of us that it was selected as the subject of a special address to-night. In one of its retired nooks I was sitting a few days ago, contemplating its past and future. I sat wondering how long it will take, and whether any of us older men will see the day, when America, after having given the political world the guiding example of a stationary popular government both conservative and perfectible, will lead the world of science, as it does that of politics, and, we hope of healthful social development; wondering, also, how much this head centre of the medical profession and this ever-growing library will contribute to that consummation, which you can hasten by industrious, honorable, and modest work—but by work only.

This library of yours has started from small beginnings, like medicine itself. It comprehends the labors of thousands of workers assiduously employed through long centuries. That one of them could be missed is difficult to say. For the co-operation of the many, the gradual development of ideas, the slow changes in experience and doctrines are of as much importance as the revolutionary and epoch-making labors of the greatest. For no single man can stand alone, a law to himself and others. Even genius is the child of its time. No Washington or Lincoln, no Hippocrates or Aristotle, no Virchow or Pasteur, or even Koch, none of these immortal ones is a world by himself, and an isolated, self-lit sun, illuminating and warming the universe. Every one has been raised on the shoulders of his predecessors. By that knowledge it is that while hope and energy are aroused, patience is taught to the individual and the profession. For while life is short, science and art are unlimited and eternal. And the comparison of what you furnish yourself with the existing mass of accumulated knowledge, inculcates modesty and enhances zealousness. Thus good citizens are made and model scientists. Besides, what to the pupil the information gathered from the lips of his master, that is for you the collective bequests of all centuries as represented in your library. Thus an intellectual kinship is formed between you the living, and the spirit of all eras of history. That is what the study of the history of medicine teaches us which we have so long neglected.

Pondering over the shelves you behold abstract scientific treatises, works on practical therapeutics, and books on art and appliances—all of them composing our beloved "medicine." Remove the theoretical works on anatomy, histology, and embryology, experimental physiology, physics, and chemistry—what remains? The wreck of the edifice, the foundation of which is torn away.

Look at the shelves holding special literature. There the specialist will comprehend that his doctrine and art are but a minimal trifle when compared with the surrounding wealth, and that the basis and link of all specialities is general medicine. Every one of them evolved from a minute bud of the great tree, and but few have ever been able to grow up with anything like independence. Thus medical science and art is shown to be an organism of slow, consistent, historical growth. Even the very excrescences—call them fallacies, superstitions, theories, schools, or sects—do not disturb the organic economy. In accordance with this, your very library, the representative and exponent of all medicine, is no longer a mere collection, but a vitalized organism.

That is why there is an atmosphere of solemnity in your large library; for you are standing in the presence of the spirit and soul of all previous ages, each evolving from and connected with its neighbor. That is why a library is to the scientists what the church is to the pious; or a museum of a hundred gems, like that which a generous fellow presented to our reception-room, to the artist No consideration of lucre invites you there. While nourishing your minds, you disconnect yourself from the embarrassments of trivial employment, and deliver yourselves from the merely terrestrial. In that way idealism is nurtured that no feeling and thinking man is to be without; idealism, without which no nation can expect to live. When she lost it, even Hellas perished, though she had given birth to Solon, Pericles, Aristides, and Sophocles.

Let me suggest this reflection as a platform, my young colleagues. It is not a dream, but a reality, if you will make it so. By so doing, not only will you elevate your august science and the noblest of all callings, but you will also remain in constant and indissoluble intellectual and moral contact with the most cultured elements of society. If you do, this evening, which is both an anniversary and an inauguration, will prove a blessing for all future to both the profession and the community. Look upon this edifice not merely as a new and commodious building, but as the visible portal into a new epoch. If you do so, you will consecrate this solemn occasion as the Fourth of July of American Medicine.

ADDRESS BY FORDYCE BARKER, M.D.

MR. PRESIDENT AND FELLOWS OF THE ACADEMY: I must detain you only a few moments on this joyous occasion, to express my warm congratulations. It is now nearly twelve years since I had the honor to first address officially the Academy, when I expressed the hope that the walls of our then home would soon be extended for our rapidly growing library. Within a few months after, by the spontaneous munificent gift of one whose name

must ever be gloriously perpetuated and now honors one of the rooms of the present building, our hall was greatly and beautifully enlarged, and met all our wants for several years, until it became apparent that we must have more room for our books and the other requirements of the Academy. To most of us this probably seemed a dim perspective in the future. Who could have anticipated so speedy and noble a result as we now see? We can now say appropriately, in a paraphase of the words which Shakespeare puts in the mouth of Gloster, in Richard III., "Now is the winter of our discontent made glorious summer," by these our sons of York, and in grateful remembrance of many of our liberal benefactors, I must add, the daughters of York. I must congratulate the Academy on its office-bearers, all of whom have worked most zealously to bring about this happy result, and especially congratulate it on its wise election of the present incumbent of the presidential chair, and his immediate predecessor, both of whom have labored together with untiring earnestness, great wisdom and tact, and fortunately both of whom possess means which they have liberally contributed to this end. I do not hesitate to express the opinion that without the combined efforts of these two gentlemen the glorious consummation which has now arrived would have been long delayed. We have now a central and spacious home in which the profession will find it pleasant and profitable to work together for mutual improvement and the public good, in the advancement of science, the promulgation of new truths, and the development of progressive skill in our art. And I will add the cultivation of those social graces which bind us in the friendly ties of a brotherhood, a noble and useful profession. We can assure the profession that they will be welcome to a library which contains the accumulated treasures of the past on every topic pertaining to medical science, and the current and periodical literature of the day, so necessary for all who would keep abreast with the present rapid advance of science. We to-night begin a new era of the New York Academy of Medicine. Who will venture to cast a horoscope of its grand future? New York, the commercial metropolis of the country, should be the metropolis of the medical thought, the medical literature, the medical teaching of the country, and to the Academy of Medicine belongs this great mission to make it so. One thing we should all remember, "that above," to quote from Webster, there is room for an additional hundred thousand volumes. Ever bearing in mind that "Concordia parvæ res crescunt; discordia maximæ dilabuntur," and the future we seek for this Academy is certain to be gained.

Clinical Department.

A CASE OF OCCLUSION OF STENO'S DUCTS.

By BRADFORD C. LOVELAND, M.D.,

CLIFTON SPRINGS, N. Y.

Mrs. F——, a woman of middle age, was sent to my office about the middle of March, 1889.

She complained of a dry mouth, and said that she had been troubled more or less with it since she had diphtheria twelve or thirteen years ago.

Her mouth was indeed dry, for, as I looked into it there seemed only a little sticky mucus about the teeth and under the tongue. And when I took hold of her lip and cheek to look for the openings of Steno's ducts, the mucous membrane wrinkled like dry tissue-paper does when stretched.

I could not at first see the openings of the ducts, and could not press any saliva out. But when she attempted to eat the parotid glands would swell up so as to make her look like a patient with the mumps.

After careful examination I found where the ducts had opened, and could only think of two ways to relieve the condition: first, to introduce a fine probe if possible; if I failed in that, to make an opening into the duct further back.

I tried a No. 1 Bowman probe, and after some difficulty succeeded in getting it in through the portion which seemed closed from strictures, one after another, for nearly three-quarters of an inch. Next day I tried the other duct, and by a little more patience was able to get it also opened.

I used the No. 1 probe for two or three days in each duct, and then No. 2, and in a few days more No. 3; and so on till I was using No. 8, which I kept using every day for a while, then every other day, and then once a week, till June 20th, when I thought it safe for her to go home and spend a few months, and come back again, which she did, returning February 1, 1890.

When she returned I could easily pass a No. 6 Bowman probe in either duct, and again dilated till I could pass a No. 8 with ease. I discharged her cured in April last, as several months had elapsed without the ducts again closing.

It was a long time after the ducts were well opened before the saliva took on a normal appearance, for at first it was about like the white of an egg, and had to be pressed out. It also contained some pus. She assured me that she had been unable to chew solid food, and had lived almost entirely on liquids, for more than a year and a half before I saw her, and had much discomfort even in taking liquid food, on account of the swelling and pain caused by the secretion of saliva, which could find no exit and had to be taken back into the tissues.

She had considerable trouble with the lymphatics of the neck as a result.

She has now been eating meat and other solid food for more than a year.

I have only seen one other case of the kind, and that was traumatic in origin and only on one side, in a boy who fell and bit his cheek, involving the duct and causing an inflammation which resulted in stricture. As he only came to me for consultation and did not stay for treatment, I do not know how it resulted.

The strictures in the case reported were probably the result of the diphtheritic inflammation, which must have extended into the ducts.

As I did not find a counterpart of the case I have reported in any of the literature at my command, I thought it might be of sufficient interest to report.

A CASE OF GRAVES' DISEASE: APPARENT HEREDITY.

By JULIUS ROSENBERG, M.D.,

HOUSE PHYSICIAN, ALMSHOUSE HOSPITAL, BLACKWELL'S ISLAND, NEW YORK.

Ellen G——, a native of Ireland, thirty-eight years of age, came under my observation about six weeks ago. She has been married twenty-five years, and was pregnant eleven times. Only the third child is living; the rest were either still born or died soon after birth. Her husband contracted syphilis some time previous to marriage, but she gives no history indicating that she ever suffered from this disease. Her father and his mother, and also his two sisters, were afflicted with what she calls "prominent eyes and swollen necks," and have died of heart disease. She has one brother and one sister, and the sister is suffering from the same deformity. Patient claims to have been in good health all her life, but says her eyes have been prominent since she was eight years of age.

At the present time patient has frequent attacks of vertigo and palpitation, and uneasy feeling referable to the heart. There is marked exophthalmus, and when she closes her eyes about one fifth of the eyeball remains exposed. The vision in the right eye is normal; the left eye is blind, the result of an injury received about three years ago. The thyroid is slightly enlarged and harder than normal. The pulse is rapid (120 to 160), com-

pressible, and very irregular. The heart is hypertrophied and displaced toward the left, apex beat diffused. The valves are normal, and there is a blowing sound heard all over the chest, and venous lines in the veins of the neck. The other organs are normal, and the urine is negative. In glancing over the literature of Graves' disease, I find heredity hardly mentioned as a factor in its etiology. The case is well marked, its long duration and the absence of any great discomfort are also of interest. I may therefore be pardoned for sending you this abstract for your perusal.

AN INTERESTING CASE OF IMPERFORATE HYMEN.

Occlusion of the vagina by an imperforate hymen is not infrequently brought to the attention of the practitioner, whose aid is sought on account of absence of the menses in adolescent girls; and, as the necessary incision into the occluding membrane is sometimes followed by the death of the patient, it is well that he should be familiar with the changes which result from the obstruction, and with the conditions which produce death in the fatal cases.

When occlusion exists, with damming back of the menstrual blood, it seems that distention of the vagina first takes place, and then of the uterus, the Fallopian tubes being the last to suffer. When, after the obstruction has continued a long time, these organs are at last affected, each tube dilates into a series of three or four distinct blood-sacs, which are separated from each other partly by lamellæ which project internally, and partly by peritonitic false membranes and bands which constrict them from without. The uterine and abdominal ends of the tube are generally both closed. If the abdominal end remains open or yields temporarily to the accumulated blood, the blood may pass into the abdominal cavity, and may, in favorable cases, be encapsulated in Douglas' cul-de-sac as a retro-uterine hæmatocele, or between the fimbriated end of the tube and the ovary.

Usually, after a considerable quantity of menstrual blood has accumulated behind the imperforate hymen, the patient begins to suffer violent paroxysms of pain at the menstrual periods. After inflammatory processes have been set up, the pains may come on at any time between the periods. When the case is at all advanced, the patient is always in danger of peritonitis, or of rupture of the sacs in the Fallopian tubes.

The comparative advantages of complete evacuation at a sitting, and of more gradual evacuation, are still under dispute, but it seems clear that, while the former is the proper method in simple cases, the latter may be preferable in cases of long standing, where permanent changes in the relation of organs and extensive adhesions have occurred.

There are two causes of death after operation, sepsis and rupture of the Fallopian sacs. The former, which is due to decomposition of the menstrual blood which is left in the uterus and vagina, may be prevented by strict cleanliness and by antiseptic irrigations. The latter is a much more serious affair, and cannot be so easily prevented, even if weakening of the thin walls of the tense tube sacs by septic processes is avoided. It is not now believed that residual blood is forced through the tubes by the contracting womb, since it has been proven that the uterine end of the tube is closed; it is known that the fatal hemorrhage or peritonitis is due to rupture of already formed tube-sacs. The rupture of these sacs is greatly favored by the removal of the abdominal pressure upon their walls which follows evacuation of the uterus and vagina, and also by the inability of the tubal sacs, which have become fastened by inflammatory bands to the surrounding parts, and especially to the peritoneum of the abdominal walls, to follow the uterus as it contracts after removal of its contents and the contents of the distended vagina. Rupture of the tube-sacs may be prevented by slow evacuation of the vaginal and uterine contents, and the application of a cotton pad to the abdomen, to replace the pressure exerted on the sacs by the evacuated blood. Perfect rest must be enforced. If the tube-sacs can be detected, they may be emptied or removed by a suitable operation.

Sometimes the pent-up fluid in the genital canal consists of a sero-mucous fluid, free from blood. This has been observed in childhood, and also at puberty.

Sometimes the retained blood has assumed a puruloid appearance, from admixture of pus as a result of inflammatory processes which have been excited. In the *American Journal of Obstetrics*, August, 1890, Dr. Kinloch relates a case of this sort. The patient, aged eighteen, complained of a small tumor in the hypogastrium, which was treated merely by painting with iodine. During absence from home for a year she neglected it, as it caused her no inconvenience. On her return it was as large as a uterus at seven months. Imperforate hymen being diagnosed, an incision was made, and a great quantity of odorless pus like fluid, showing under the microscope pus-and blood-cells, was evacuated. The cavity, which had walls like an abscess, and which lay chiefly in the vagina, was emptied at once under antisepsis and a drainage-tube was introduced. The patient made a rapid recovery.

Progress of Medical Science.

Subcutaneous Injections of Water in large Quantities.—Professor Sahli, of Berne, has published a paper in which he forcibly draws attention to a simple method of rapid and safe introduction of large quantities of water into the system. The method consists in the subcutaneous injection of a sterilized blood-warm physiological saline solution (that is, a 0.73 per cent. solution of chloride of sodium) by means of a large Erlenmeyer's flask, with an elastic tube and a hollow needle as thick as a knitting-needle. As much as one quart of the solution can be easily injected in from five to fifteen minutes. If necessary, the procedure may be safely repeated four or five times a day. The best situation for the injection is the anterior abdominal wall. On each occasion the skin should previously be thoroughly washed with soap and corrosive sublimate, and the puncture subsequently sealed with aseptic cotton-wool and collodion. Under such precautions not the slightest signs of any local reaction are ever observed. In some patients, especially in those with flabby abdominal integuments, the procedure causes but trifling pain; in very sensitive or restless persons, however, general anæsthesia is advisable. The effects of the injections are thought to be as follows: 1. Under certain conditions they thoroughly wash out the patient's system by inducing profuse diuresis accompanied by a strikingly increased elimination of solid constituents of the urine. 2. They dilute the body juices and poisonous substances present therein. 3. They furnish the necessary water supply to dehydrated tissues. 4. They aid the filling up of blood-vessels, and thus raise an unduly lowered arterial tension. Such subcutaneous injection of water is indicated: 1. In cases of uræmia complicating the course of either acute or chronic nephritis, where the injection of a litre of the solution once or twice daily is, as a rule, rapidly followed by a striking abatement of all symptoms. The best results, however, are frequently obtained when the injections are combined with the internal administration of digitalis. 2. In the "typhoid" state, where frequently even after the very first injection delirium ceases, the pulse becomes stronger and fuller, the tongue moister, etc. 3. In Asiatic cholera, cholera nostras, infantile diarrhœa. 4. In poisoning by any toxic substances, but especially by those which are liable to be eliminated from the organisms through the kidneys. 5. In cases where an internal use of water should be avoided (in order to secure physiological rest of the gastro-intestinal tract)—

for instance, in cases of perforation of the stomach or bowel, peritonitis, ileus, etc. 6. In cases of acute anæmia from hæmorrhage. The method is contraindicated (1) in cases of incipient or expected pulmonary œdema; and (2) in the presence of severe dropsy.—*British Medical Journal*, September 20, 1890.

Aprosexia in Children.— Mr. Shaw states that in the aural out-patient practice of several large hospitals, he has made inquiries from the mothers who have brought children to be treated for deafness as to the mental acuteness of these children, and he was struck by the frequency of the statement that with the onset of deafness the children became much duller mentally and showed a marked change in their capacity for schoolwork (*The London Medical Recorder*). On further investigation the author found that when this dulness had been noticed there was invariably present an overgrowth of adenoid tissue of the pharyngeal tonsils, and in the immediate neighborhood of the orifice of the Eustachian tube. On removing this growth, or even on scarification, the deafness was relieved, and at the same time an improvement was noticed in the mental capacity of the child. In 1887, Professor Guye, of Amsterdam, drew attention to this particular class of cases, and revived the use of the word "aprosexia," which is the Greek for "heedlessness." Professor Guye attributed the mental condition in these cases to a supposed congestion of the intracranial venous and lymphatic systems, caused by the enlargement of the lymphatic glands in the neighborhood of the pharynx and nose, which are in connection with the lymphatics of the anterior lobes of the brain. Ferrier has shown that in the monkey extirpation of the pre-frontal lobes of the brain has been followed by a marked impairment of the faculties of attention and observation. Co-existent with the hypertrophy of lymphoid tissue, which produces the "adenoid vegetation," there is found an increase of the more purely fibrous connective-tissue element in the neighborhood; this has a tendency to contract, and so causes compression of the lymphatics, and obstructs the flow of lymph, so that the waste-tissue products, derived from the metabolism going on in the cortex of the fore brain, are prevented from making their escape, and remain in the cerebral cortex, interfering with and hindering its proper nutrition, the resulting malnutrition giving rise to the condition which is termed "aprosexia."

Wandering Rash on Children's Tongues.—At a recent meeting of the Calcutta Medical Society, Dr. Towers showed a case of this kind. He said it was a condition of the dorsum of the tongue which has only of late years been differentiated as a distinct affection. Other names for it are "ringworm, circular exfoliations, geographical tongue, etc." It is well described and depicted in Butin's "Diseases of the Tongue." The characters of the rash are, that it is met with chiefly in children, that it seldom gives rise to disagreeable symptoms, that it is unaffected by treatment, that its area and distribution are subject to constant changes, that it is apt to persist for a long time, and ultimately to disappear spontaneously. It consists of one or more circinate patches on the dorsum, of various sizes, separate, or confluent, smooth, red, and on the same level as the surrounding surface, with a distinct whitish or yellowish border. The filiform papillæ have been shed, but the fungiform distinctly remain. Rings may form within rings. It commences always on the dorsum. On account of the few subjective symptoms it is usually discovered by accident. The cause of the disease is unknown, but it appears to be associated with debility. It has to be differentiated from syphilitic mucous patches, leucoma, and ichthyosis. In syphilis the patches are distinctly raised above the surrounding surface and are grayish upon their surface, and there are present other signs of syphilis. Leucoma is a disease of adults, and consists of pearly patches with red borders and bases. Moreover, leucomatous patches do not change from day to day. Ichthyosis is also a disease of adults, and consists of patches of hypertrophied filiform papillæ, while just the opposite condition obtains in this affection.—*Indian Medical Gazette.*

Euphorine.—Under the name of euphorine Dr. Sansoni describes the physical and therapeutical properties of a new compound which, chemically, is phenylurethan. It is a white crystalline powder, with a faint aromatic odor and a slight taste suggesting that of cloves. It is sparingly soluble in cold water, readily dissolves in alcohol, and is best administered in white wine, in which it is easily dissolved. Given to healthy men, in doses of from 1½ to 3 grains, euphorine has no apparent effect upon the pulse, the respiration, or the temperature; and in dogs large doses do not lower the blood-pressure, as determined by the manometer. Still more important is the fact that it causes no changes in the blood—in animals the blood remaining normal even after toxic doses have been given. Clinically, Sansoni finds that euphorine possesses valuable antipyretic, antiseptic, antirheumatic, and, in some cases, analgesic effects. As an antipyretic, he has employed the drug in fever from various causes, such as typhoid fever, croupous pneumonia, phthisis, acute rheumatism, pleurisy, orchitis, influenza, etc., administering it either as a powder or dissolved in wine. The fall of temperature begins within an hour after the administration, reaches its maximum usually in about three hours, and continues, as a rule, for from five to seven hours. In some cases the fall is more brief, and in a few it continues for fourteen hours. The subsequent rise of temperature is usually sudden and accompanied with a chill, the duration and severity of which are proportionate to the intensity of the disease. During the period of apyrexia the patient has a feeling of well-being. Cyanosis is seldom observed, and the pulse and respiration are regular. The antipyretic effect varies in different persons, and it is best to begin with a small dose (½ grain), increasing until the proper amount is determined. To most adults, from 15 to 22 grains can be given daily without producing harmful effects, its antithermic power being about twice that of antipyrine. In rheumatism, both acute and chronic, the doses of euphorine should be larger than those given to reduce temperature. From 22 to 30 grains, or even more, should be given daily. In acute rheumatism the good effects appear very soon after the drug has been administered; the temperature falls, and the pain, whether due to inflammation or to the pressure of the swelling, disappears. As an analgesic, euphorine is very useful in orchitis, less so in sciatica, lightning pains of tabes, and trigeminal neuralgia, and is almost useless in intercostal neuralgia and migraine. The observation that carbolic acid is formed when euphorine is brought in contact with an alkali, led Sansoni to test its antiseptic powers, which, in the case of an obstinate ulcer and one of chronic ophthalmia, he found were excellent.—*Medical News*, October 11, 1890.

Antiseptics among the Ancient Greeks.—Professor Anagostakis, of Athens, has published some interesting facts in reference to the employment of antiseptic measures among the ancient Greeks. Hippocrates and Galen were aware that an unclean condition of wounds retarded healing. They were also well acquainted with the fact that by thorough hæmostasis, suture, and the employment of antiseptic measures, infection of wounds might be prevented. Hippocrates warned his disciples against the use of moist dressings, on account of the danger of suppuration, and forbade the employment of drugs before the wound was dry. Above all, says Galen, avoid dirt, as it prevents healing. The ancient Greeks boiled their water before applying it to wounds. Sponges were avoided, and charpie recommended in their stead, which was to be destroyed after use. One of the principal antiseptic substances then in use was wine, which was usually heated before using, and with which, according to Hippocrates, all wounds were to be washed Dressings dipped in wine

were also applied to the wound. Salt was in very general use, either in solution or in the form of sea-water. The solutions were rendered aseptic by boiling. Sulphate of copper was relied upon as an antiseptic for foul wounds, and was also put into use as a hæmostatic. Tar was highly praised for its antiseptic virtues, and was either applied in the form of a dressing or directly poured upon the wound. Besides these, many aromatics and bitters were in daily usage, among which were thyme, rosin, asphaltum, etc., used as dressings, or in the form of plasters. Galen was acquainted with catgut, and advised the use of non-putrefying substances for sutures. Professor Anagostakis declares that all this was not empiricism, but an antiseptic method founded upon some knowledge of the principles governing the healing of wounds.—*Druggists' Circular.*

Some Anomalies of Secretion of the Mammary Glands.—After referring to the repeatedly observed phenomena, in the animal and human subject, in which the male glands secreted milk copiously, Dr. Landau lays stress upon the importance of recognizing not only the qualitative fluctuations in the milk of nursing women, but also the great difference which frequently exists between the milk secreted by the two glands in the same individual. He has seen cases in which the secretion from one breast was sweet, that of the other being just as copious and rich, but having a salt taste. Diseased conditions of the subject have a powerful influence upon the character of the secretion, yet it is not so profoundly altered as not to be termed milk in a chemical sense. With vicarious menstruation the most pronounced changes take place. One case under the observation of Landau has monthly flows of blood from both mammæ. The appearance of abnormal secretion from the mammary glands must be regarded as of evil import, not infrequently constituting a symptom of malignant growth in the gland. Three cases were observed by the author in which abnormal secretion took place from one breast in women at the menopause. In one the patient found that every morning the night-dress was soiled on the left side of the chest with what she supposed was matter; shortly before and during the menstruation the secretion became more copious; gradually the originally yellowish-white fluid became darker, and was finally dull black. Her physician injected some substance—probably iodine tincture—which caused the secretion to cease for two weeks, only to reappear with wonted characteristics. The left breast was uniformly softer than the right. Microscopically, the fluid was seen to contain numerous blood-disks, colostrum bodies, free fat-globules, and a few lymphoid cells; epithelial cells and crystals were wanting. Reaction was neutral It was concluded that the fluid was a mixture of milk with some blood. Patient's health was excellent. A compression bandage was placed over the breast; three days later there was not a drop of the fluid secreted. He considered this case simply one of late lactation; it may be that through the congestion of the gland its vessels became engorged, and that blood disks found their way into the milk channels by diapedesis through the lymphatics. The bandaging caused the spontaneous flow of the fluid to cease.—*American Journal of Obstetrics*, October, 1890.

Laparotomy for Tubercular Peritonitis.—A paper on this subject by Dr. Wheeler (*The Breton Medical and Surgical Journal*, September 11, 1890) concludes as follows: "The calm facts are that certain cases of tubercular peritonitis are open to surgical cure. Although no general cure has been discovered, a step in advance has been made. Now as to the kind of case which promises good results after operation. Not all cases of tubercular peritonitis are to be operated on, by any means. A certain number get completely well without operation, and another number is outside the possibility of help A certain group of cases are unhesitatingly to be operated upon, another group are to be unhesitatingly let alone, while in others the question must be decided on individual merits. It is impossible to settle the question by tables of symptoms, but the author enumerates a few of the indications and contra indications, prefacing that the general condition of the patient will perhaps settle the question of operation or no operation, as often as anything. First. Indicating operation: 1. Abundant ascites. 2. Absence of small amount of solid masses. 3. Disease primary in the peritoneum, though the mere presence of tuberculosis elsewhere does not forbid operation. Some cases have apparently recovered entirely, when there was slight co-existing disease of the lung, both peritoneum and lung becoming healthy. 4. Encysted disease, that is, serous or purulent pockets. 5. Intestinal obstruction. In the last two, operation is imperative. On the other hand, contra-indicating operation: 1. Absence of ascites. 2. Abundant masses or strands. 3. Secondary to advanced general tuberculosis. 4. Intestinal ulcers. The last two forbid operation. As to method of operating. The abdomen should be cleaned out as well as possible, by flushing with hot water and sponging; separating meanwhile any adhesions which can be broken without injury to the viscera. No antiseptic and no drain, unless for some special reason, as for instance, hemorrhage. Tapping should not be practised. There is danger of doing harm, and it cannot do so much good as laparotomy."

Resection of the Cæcum for Carcinoma.—Dr. Senn (*Journal of the American Medical Association*) announces the following conclusions on this subject: 1. Resection of the cæcum for carcinoma can be done with a fair prospect of a permanent cure if the operation is performed before infiltration of the retro-peritoneal and mesenteric glands has occurred. 2. Ileo-colostomy with absorbable perforated approximation plates is the best method of restoring the continuity of the intestinal canal after excision of the cæcum. 3. The best material for approximation-plates is decalcified bone preserved in an antiseptic solution. 4. Hygroscopic and indestructible or inabsorbable material should not be used in the preparation of approximation-plates or rings, as the former may cause pressure-gangrene, and the latter may prove a source of danger by remaining permanently as a foreign body in the organ in which it has been introduced. 5. Ileo-colostomy without resection of the cæcum is indicated in cases of intestinal obstruction from inoperable carcinoma of the cæcum, irreducible invagination without perforation or evidences of gangrene, and in cicatricial stenosis in the ileo-cæcal region not amenable to a plastic operation. 6. Scarification of the serous surfaces interposed between the bone-plates is the most reliable means of hastening the formation of adhesions and of shortening the process of definitive healing. 7. Resection of the cæcum and ileo-colostomy, with or without enterectomy, should be done through a lateral incision, extending from near the middle of Poupart's ligament to a point half-way between the anterior superior spinous process of the ilium and the umbilicus. 8. Suturing of the serous surfaces just beyond the margins of the bone-plates renders material aid in maintaining apposition between the serous surfaces which it is intended to unite, and furnishes an additional safeguard against fecal extravasation. 9. Anchoring of the approximated parts in the ileo cæcal region with a mesenteric-peritoneal suture should be done in ileo-colostomy after resection of the cæcum.

The Catalogue of a Bogus Medical College has fallen into the hands of a daily paper, which has attempted an investigation. It is called the Union Medical Institute, and is situated in a small Vermont town. It is not incorporated and owns no building. The Faculty seems to consist of a very mixed company, containing among others a telegraph operator, a newspaper reporter, and some doctors of doubtful title living several hundred miles away.—*Boston Medical and Surgical Journal.*

New York, November 29, 1890.

THE CLIMATOLOGY OF BRIGHT'S DISEASE.

DR. CHARLES W. PURDY, of Chicago, has made a study of the influence of climate in the United States over Bright's disease (*New York Medical Journal*, October 4, 1890). His work is based upon the statistics of the Tenth Census, according to which there were, in 1880, 75,386 deaths from the disorder in question, giving a ratio of 7.11 to every thousand deaths. This figure Dr. Purdy takes to represent the average for the country. Starting with such an assumption, he finds that in New Jersey, New York, Connecticut, Massachusetts, and New Hampshire, the average is exceeded two to four times. On the other hand, in the States of Tennessee, Georgia, Nebraska, North Carolina, and Arkansas, the ratio is from three to four times below the average.

Taking the country by districts, it is found that Bright's disease attains its highest mortality in the middle Atlantic coast region—19.73 in 1,000—or considerably over two and a half times more than the average for the whole country. The North Atlantic coast region comes next in order, the ratio being 17.38 in 1,000. The north-eastern hills and plateaus furnish the next highest ratio—11.20 in 1,000 deaths. The average for the three regions just named is 16.15 in 1,000—or nearly two and a half times higher than the average for the whole country.

Dr. Purdy thinks that his statistical inquiries justify the following conclusions:

1. That the chief features of climate in the United States which most strongly tend to increase the death-rate from Bright's disease are cold, moisture, and changeability of temperature.

2. That the elements of climate which tend in the greatest degree to decrease the death-rate from Bright's disease are warmth, dryness, and equability.

3. That cold most markedly increases the mortality from Bright's disease when associated with moisture, a comparatively low temperature being well borne if the atmosphere is a dry one.

4. That a comparatively high degree of humidity of the atmosphere does not markedly increase the mortality from Bright's disease if accompanied by warmth and equability.

5. That the most unfavorable residence localities for patients afflicted with Bright's disease in the United States are comprised within the Atlantic coast region and north-eastern hills, which include the States of New Jersey, New York, Connecticut, Massachusetts, New Hampshire, and Vermont.

6. That the most favorable residence localities are chiefly comprised within the Southern interior, and especially include the States of Tennessee, Georgia, North Carolina, Arkansas, and Texas.

The general correctness of the foregoing will not probably be questioned. Long ago, Lombard, in his "Climatologie Médicale," showed that Bright's disease was rare in extreme northern regions, frequent in the temperate zone, and comparatively rare, with striking local exceptions, in tropical regions. It is, for example, said to be frequent in parts of India.

There are other elements than the purely climatic or meteorological, however, which aid in determining the local prominence of this disease. Race has apparently a decided influence. The Irish, for example, seem to be especially susceptible to the disease in this locality. In New York City, which has the enormous death-rate from Bright's disease of 60 per 1,000, over half the deaths are among the foreign-born. On the other hand, the death-rate from Bright's disease among negroes is very low, being, as near as can be estimated, at least one-half less than the average. This would considerably influence the mortality-rate in the South.

One factor not mentioned by Dr. Purdy, which has long been recognized as influencing the production of Bright's disease, is the prevalence of malaria, and this may explain the predominance of the disease in certain parts of the South.

Finally, it is an unfortunate fact that the vital statistics of the Tenth Census are extremely incomplete and untrustworthy, especially as regards the South. So that, on the whole, we could not place much confidence in the conclusions drawn by Dr. Purdy, if they were not more or less borne out by the general clinical experience of the profession.

LUPUS VULGARIS.

LUPUS VULGARIS, of which we are now hearing so much, is an extremely chronic disease of the skin, attacking persons between the ages of two and fifteen. It is characterized, says Green, by the appearance of reddish-brown nodules of granulation-tissue upon the skin, usually of the face. The mucous membranes are rarely affected. The nodules start in the corium, but penetrate the connective tissue beneath and the papillary layer above. The different stages and clinical aspects of the disease as it progresses are known as lupus maculatus, lupus exfoliativus, lupus exulcerans, lupus serpiginosus, and lupus hypertrophicus.

The disease spreads by the formation of fresh nodules at the periphery of the original lesion. New centres form and the old ones may gradually disappear. If the tissue breaks down an open sore is found, covered with yellowish and brownish crusts.

The nodules consist of granulation-tissue, containing epithelioid and a few giant cells. Unlike ordinary tubercle, the lupus nodules are rather vascular. Tubercle bacilli are found in the tissue, but they are very infrequent, and often many examinations are required to detect them. Inoculation of lupus nodules will, it is asserted, cause tuberculosis in rabbits and guinea-pigs; but

noculation of the skin with tubercle will not produce lupus.

For this and other reasons so distinguished an authority as Kaposi denies that lupus is a cutaneous tuberculosis, although that view is held positively by Koch and his pupils.

Lupus, chronic as it is in its tendencies, often disappears for a time under treatment, only to reappear later. Dermatologists generally give a favorable prognosis, provided treatment is persisted in.

THE CARE OF THE PRIVATE INSANE.

SINCE the passage of the New York State law for the care of the insane poor, a serious question has arisen regarding the proper treatment of such insane persons as are neither poor nor rich, but who have, at reasonable rates, been allowed the privilege of the State institutions. The Chief Commissioner of Lunacy, Dr. Carlos F. MacDonald, in connection with the Board of Lunacy, is very properly inclined to interpret the law in its literal sense and act accordingly. In future, then, no patient can be admitted into any State institution as a private individual, paying his or her board. While this may remedy what in some of the asylums of the State has heretofore grown to be an abuse, it will doubtless bear heavily upon the middling classes of insane, who at present have no means of being cared for outside of the private and high-priced asylums. What shall be done with these unfortunates is still open to serious question. It might be well to suggest that the State take a hand also in the solution of this part of the problem, by creating extra asylums which should be absolutely self-supporting, and in which accommodations can be obtained at merely cost rates.

USEFUL ATHLETICS.

A STORY with a pathetic leaning has appeared in a recent issue of a leading newspaper, detailing the case of a rich invalid lady who was suddenly reduced to poverty, and whose changed condition demanded the performance of her own household duties. As if, however, to prove that all evil is not unmixed with good, we are informed that by the forced exercise of her new functions at the wash-tub, the ironing-board, and the cooking-range, she became strong, her aches disappeared, and her sleep was sound and refreshing. Although it was extremely sad that the calamity of forced work should have fallen upon such a delicacy of feminity as possessed by the unfortunate subject of this healthful moral, all of her friends stand ready to congratulate her on the change so radically wrought. Although the wash-tub, broom-handle, and scrub-brush are not in the category of apparatus for the treatment of neurasthenia and its thousand and one accessory symptoms, we should not be slow to take the hint of their indications. The drill of the broom-handle may yet be found efficacious in straightening curved spines, the wash tub in expanding chests, the clothes-wringer in massaging imprisoned ovaries, and the scrub-brush in correcting retroversions.

Dr. Koch has been presented with the Grand Cross of the Order of the Eagle.

News of the Week.

New Regulations for the Care of the Insane.—The New York State Commission in Lunacy has adopted two new orders. The first provides that each insane patient shall be permitted to write to some friend or relative at least every two weeks, and in the case of patients unable for any cause to write, the medical superintendent of any State hospital must direct some proper person to write for such patients at suitable intervals, if they so desire. All letters of insane patients which are detained must be forwarded to the commission, accompanied by a statement of the reasons for such detention. All letters addressed to State officers, judges of courts of record, and district attorneys must be immediately forwarded without examination, and where the insane patient is unable to pay the postage it must be furnished by the institution. The second order states that no insane patient, while in the custody of an institution, shall be permitted to go upon parole who, in the judgment of the medical superintendent, is dangerous, either to himself or others; that no parole be granted for a greater period than thirty days; that upon the escape of a patient prompt and vigorous measures be taken to secure his return; and that a patient who has been paroled or has escaped, if not returned to the institution on the thirtieth day thereafter, must be discharged from the books of the institution upon that day, and a notice of such discharge must be forwarded to the commission, and such patient must not be readmitted except upon a new medical certificate of lunacy, the cost of which, and of the return of the patient (except in the case of a private institution by special agreement), must be borne by the institution.

The Preparation of Koch's Lymph.—The *Berliner Tageblatt* says: "The preparation of Professor Koch's curative lymph is proceeding rapidly, but the quantity required for hospitals and medical associations cannot be made ready before the end of January. The attempts that have been made to imitate the lymph justify the adoption of severe measures against the imitators. The lymph is now available for use in most of the Berlin hospitals. At the University Hospital the doctors limit the use of the remedy to persons who are strong enough to come to get an injection. All money realized from the sale of the lymph goes into the funds of the Hygienic Office."

Later Opinions on the Value of Koch's Discovery.—Professor Virchow defends Professor Koch against the charge of prematurely publishing his discovery. Professor Koch, he says, only consented to the disclosures already made at the request of Minister von Gossler and several of his medical colleagues, Doctors Virchow, Levy, and Bergmann. Everyone in Professor Koch's confidence supports his protest against the sensational expectations regarding the results of the remedy. Professor Stellwag, of the Vienna University, addressing the students, advised them to be cautious in expectance, believing only what Professor Koch has directly stated. "So far," added Professor Stellwag, "the possibility of the cure of lupus alone has been proved, while it has not been scientifically established that lupus arises from the same bacillus that is associated with lung tuber-

cles." Dr. Ullmann writes: "It will take fully a year of frequent injections, besides treatment under right sanitary conditions, to enable one to form a reliable opinion as to the curability of consumption, either in advanced or in early stages." Doctor Ullmann worked for several months in Professor Koch's laboratory. He believes the remedy promises good results in cases of external tuberculosis, although, he says, relapses must be guarded against. Doctor Surycki, reporting to the Medical Society of Cracow, which sent him to Berlin to investigate, declares that even the cure of external tuberculosis by the new process is uncertain, while he sees no grounds for believing that it will cure consumption in any stage. Doctor Kraus, of Vienna, affirms the benefit of the remedy for tuberculosis of the bones, skin, and joints, but does not believe that it will ever heal lung tubercles. Doctor Kraus was in attendance in Berlin for several weeks, testing the experiments. Professors Fraenzel and Runkuritz, in their latest report, confirm the opinion that the injections do not materially check advanced phthisis. They do, however, arrest early phthisis, but the bacilli may revive and reinfect the tissues. The opinions of a number of other experts—German, Austrian, and English—all of the same tenor, are becoming known, and tone down the excited public expectations.

Medical Statistics of Berlin.—In the beginning of this year the population of Berlin was over a million and a half, the number of its physicians and surgeons 1,398, of its dentists 107, of its privileged pharmacies 120, and of its hospitals 34, with 4,635 beds.

A Paper Entitled "The First Post-mortem Performed in New England," was read by its author, C. J. Hoadley, librarian at the Capitol, before the Hartford (Conn.) Medical Society. It described the post-mortem appearances found on the body of a child, eight years of age, Elizabeth Kelly by name, who died in March, 1662. The child evidently died of some acute disease, but her death was ascribed to the malignant influences of witchcraft. The accusedgude wife Ayers and her husband had to fly from their home, lest they should be made to suffer the penalty of the charge, which was hanging. They left behind them a child, who became the ancestor of one of the present families of Hartford.– *Boston Medical and Surgical Journal.*

How to Keep Out Undesirable Immigrants.—The report of Surgeon-General Hamilton on the subject of immigrant inspection is worthy of careful consideration by Congress and the people of this country. General Hamilton has visited the principal ports of Europe from which the great flood of our immigration flows, and while he found no reason to believe that emigrants were "assisted" to any great extent to sail for this country, his observation showed that the "inspection" supposed to be made by the steamship companies was of no practical value as a restrictive measure. In New York the inspection of arriving immigrants is comparatively strict; but even here lunatics and idiots have been allowed to land in spite of the inspection. The Surgeon-General thinks that many undesirable immigrants reach here by way of Canada, less care being exercised on our northern border than on the steamships that come directly here from European ports. He suggests a preventive measure which, if not absolutely perfect, would prove a long step toward the restriction that is becoming day by day more necessary. His plan is to oblige every intending emigrant to file before the United States consul of the port from which he sails evidence from the local authorities that he has never been convicted of crime, and that he has never been a charge on his native country, with the certificate of a resident physician that he is not afflicted with any contagious disease. On filing this the consul is to furnish him a certificate of character, so to speak, which entitles him to enter the country, and which is to be taken from him by the proper official on his arrival and filed for future reference. This certificate is to be produced, if called for, on his application for naturalization. Such a system as this would certainly prevent the entrance of thousands of objectionable immigrants, while it would open wide the doors of our national hospitality to desirable classes of foreigners.—*New York Times.*

Some of the Students at the Woman's Medical College, Philadelphia, want to abolish the regulation white silk dresses on Commencement day, and wear instead the dignified gown and scholarly mortar-board; others want to have the white robes. The Faculty is nearly as much disturbed in finding a solution for the all-absorbing problem as the girls are. A member of the Faculty has said that there is no predicting when the question will be settled.

The Meetings of Medical Men have often aroused enthusiasm and provoked eloquence, but the recent meeting of the Mississippi Valley Medical Association has made the *American Practitioner and News* poetic. After quoting Whittier and Byron, our esteemed contemporary concludes: "The 1890 meeting of this representative body of medical men is a sweet fragrance in local professional memory. It will be thrice welcome when it comes again." We wish that all medical meetings would leave behind them memories so pleasant.

A Visit Postponed.—The *Journal of the American Medical Association* contains the following: "It had been very generally announced that Sir Morell Mackenzie would visit America, and lecture in some of our principal cities during the fall. It is now reported that, by reason of ill-health, he is obliged to cancel his engagements, and defer his visit until some later day."

A Doctor Sues a Doctor for Medical Attendance.—It is a recognized custom, as between *confrères*, that no charge is made for medical services, but it must, of course, be borne in mind that this is an act of courtesy and does not disqualify a practitioner from making a charge, should he think fit so to do. Under any circumstances there is a limit, and we think that the privilege should only be held to extend to men actually in practice. These reflections are suggested by the report of some proceedings in the Dover County Court, brought by Mr. Long, a local practitioner, against Dr. Chittenden, a medical man who has retired from the exercise of his profession. Dr. Chittenden was condemned to pay the sum claimed (twenty guineas), plus the costs, so that the next time he requires professional assistance he will at any rate know what he is about.—*Medical Press.*

Reviews and Notices of Books.

Diseases of the Rectum and Anus: their Pathology, Diagnosis, and Treatment. By Charles B. Kelsey, A.B., M.D. Professor Diseases of Rectum, New York Post Graduate School, etc. Third edition. 8vo, pp. 483. New York: William Wood & Co. 1890.

The third edition of this well-known treatise makes its appearance with many additions which add greatly to its value as a guide to the advanced student of rectal diseases. The terse and perspicuous style of the author enables him to compress a vast amount of practical information in a comparatively small compass. His extensive experience is formulated in a direct and convincing way to the reader, and altogether there is an individuality about the work which gives it its chief excellence. The principles of practice laid down are eminently sound and judiciously conservative. This is especially true with the major operations for the relief of malignant disease and other equally formidable conditions. Notwithstanding the claims of success of the bolder operators in connection with formidable procedures for extirpation of large portions of the rectum, he wisely clings to the older and more acceptable method of surgical interference. For instance, Kraske's operation does not find favor with him, and he still very properly advocates the old principle of restricting extirpation to those cases in which only four inches of the gut is involved in the diseased process. This advice is eminently safe, and will so be considered by every surgeon of experience in those lines of work. His preference for colotomy, as a means of safe relief in such cases, is what would be naturally anticipated under the circumstances. The other portions of the volume are equally practical and interesting, the author losing no opportunity of enforcing the essential methods of treatment as applied to the varied forms of rectal troubles.

A Text-book on Diseases of the Eye. By Henry D. Noyes, A.M., M.D., Professor of Ophthalmology and Otology in Bellevue Hospital Medical College; Executive Surgeon to the New York Eye and Ear Infirmary, etc. Illustrated by 6 Chromo-lithographic Plates, 5 Plates in Black, and 236 Wood-engravings. Pp. 733. New York: William Wood & Co. 1890.

This work is an elaboration of a treatise on diseases of the eye, published in 1881, in Wood's "Library of Standard Medical Authors." It is divided into two parts: the first part takes up the general anatomy and physiology of the eye, its functional disorders, methods of examination, and the use of the ophthalmoscope; while the second part considers the inflammations and textural changes of the different ocular tissues. The second part, comprising nearly three-fourths of the volume, is obviously of most practical interest to the medical practitioner. In it the structural diseases are discussed in an almost perfect anatomical sequence of tissues. While disturbances involving refraction, accommodation, and motility, as also the operative surgery of the eye, will always especially interest the practitioner in ophthalmology, this book emphasizes the necessity of a thorough acquaintance with the ophthalmoscope, as essential to a confirmation of what the general practitioner wants to know. Some of the most interesting chapters are those in what may be styled medical ophthalmic practice; or the participation of the eye in affections of the kidneys, heart, uterus, and in those reflexes in which this organ has been thought to play an important part.

Under the head of asthenopia and muscular insufficiency the author writes with his well-known clinical discrimination. He prefers full correction of the optical anomaly by the judicious use of prisms. As tenotomy has lately come to the fore, the literature of this surgical procedure is briefly reviewed. It will, perhaps, be a surprise to learn that in 1841 the French surgeons, Bonnet, Guérin, and others, employed tenotomy for the relief of asthenopic symptoms. Graefe, however, in 1869, first intelligently adapted its use to deficiency of adduction in myopia. Complete tenotomy was usually the practice of the elder Graefe, while Albrecht Graefe, Abadie, and others employed partial tenotomy; lately Stevens has very largely practised what he prefers to call "graduated tenotomy," or the repeated division of small parts of the tendon at intervals of a few weeks or months. Our author prefers complete tenotomy if this procedure is to be resorted to, and controls its effect by a suture. He has had no experience with the repeated partial tenotomy, as done by Stevens. As to which operation is best, and as to the general question of surgical interference, no definite rules can be given.

The author gives precise details as to the surgical steps for extraction of cataract, and the management and behavior of such convalescents are graphically sketched. The careful writing of this chapter, the judicious display of the instruments required, and the dangers to be avoided in operating, must make this chapter most attractive to the ophthalmic surgeon. As to whether the extraction of hard cataract shall be done with or without iridectomy, only large experience can decide. The omission of iridectomy is just now popular. This largely does away with the possibility of damage occurring from irido-cyclitis and deeper-seated inflammations; on the other hand, prolapse of iris and a cystoid scar may result when no iridectomy is performed. Author states the rule that it is better to do iridectomy if the tension of the eye be great. He concludes that the operation may in the future be done without iridectomy in the majority of cases, while in special cases excision of iris will be practised.

Lack of space will not allow a more extended critical review of this volume. It is one of the best, as also one of the fullest, books in ophthalmology, or, more strictly, in ophthalmological diseases, in the English tongue. While it cannot be said that just at present a new treatise was necessary, it may easily be said that a studious perusal of the chapters of Dr. Noyes's book will prepare one with what is not only current, but with what is also best, in ophthalmic science.

The publishers have been most liberal in the number and quality of the illustrations; all in all, the appearance of the work is highly fortunate and opportune.

The Throat and Nose, and their Diseases. By Lennox Browne, F.R.C.S.E., Senior Surgeon to the Central London Throat and Ear Hospital, etc. Third edition. 8vo, pp. 690. Philadelphia: Lea Brothers & Co.

The author has taken great pains to make the successive editions of his work acceptable to the profession, by keeping it abreast of the voluminous literature of his subjects. The second edition was virtually rewritten, and the third, which is before us, is replete with new things, and fully sustains the author's reputation for faithful and conscientious work in his specialty. In the present edition the diseases of the nasal fossæ are more elaborately treated than formerly, and give a corresponding importance to that part of the treatise. A peculiar and valuable feature of the work is the number of accurate and finely illustrated pathological appearances of the different diseases of the throat and fauces, all drawn from nature by the author, and all more or less typical in character. The work has unquestionably secured for itself the position in the first rank of authoritative ones in the specialty.

A New Method of Bleeding in Pulmonary Congestion.—Dr. J. C. Simpson (*Lancet*) reports four cases of pulmonary congestion in which he drew blood from the lungs by driving an aspirator needle directly into the tissue, withdrawing it, and then letting the blood flow out through a cannula. The operations were successful, though the patients all eventually died from other causes.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

OPENING OF THE NEW BUILDING, NOVEMBER 20, 1890.

ALFRED L. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

THE meeting being the opening reception in the new building, 17 West Forty-third Street, it was largely attended by both the profession and the laity. Over a thousand people were present. The programme of exercises included an invocation by Rev. Howard Crosby, D.D.; an address by the President; the anniversary oration, "The New York Academy of Medicine," by Edward L. Keyes, M.D.; an address, "Our Library," by A. Jacobi, M.D.; and an address by Fordyce Barker, M.D. The addresses and the oration appear in this number of the MEDICAL RECORD. There were also addresses of congratulation from neighboring cities by Drs. John S. Billings, U. S. A., S Weir Mitchell, and Reginald H. Fitz. The exercises were interspersed with music and closed by a collation.

MR. D. WILLIS JAMES, who was to have delivered an address, "The Influence of Scientific Associations upon Great Cities," sent a letter regretting his inability to be present, and stating further: "New York cannot learn too soon the fact that a great imperial city cannot be built on material prosperity alone. The foundations must be deeper, broader, and more enduring. Years ago, in the city of Wurzburg, I was deeply impressed by the fact that the magnificent palace begun centuries ago as a home for regal magnificence, luxury, and display, was going to decay and was shrouded in gloom, while a hospital started at the same time, to be of service to the needy and the suffering, was, after the lapse of the centuries, doing its beneficent and holy work, and out of which had sprung a medical college, the fame of its distinguished professors drawing crowds to the city.

"If New York is to be the great imperial city of the future, we must see to it now that we plant and foster not only churches and schools, hospitals, art galleries, and parks, but also great universities, largely endowed, and, as most important parts of these universities, medical colleges, magnificently and munificently endowed, so that they shall have every possible facility for accomplishing the best work. . . . Looking at the magnificent work the medical profession have done and are doing, remembering all they are accomplishing for suffering humanity, stirred as our enthusiasm is by the discoveries of such men as Professor Koch, of Berlin, with their promise of lasting benefit to humanity, let us, as citizens of New York, see to it that in our midst the means are amply and promptly supplied for the most complete scientific research in all departments of learning, but especially in medical science."

Congratulations from Washington.—DR. JOHN S. BILLINGS, U. S. A., said he esteemed it a great privilege to be present on this occasion, and congratulated the fellows of the Academy most warmly and heartily upon their acquirement of a permanent home. He offered these congratulations not only as an individual warmly interested in the progress of the work of the Academy, but in behalf of the medical officers of the army, and of other departments of the Government, who of late years had experienced much hospitality and courtesy in the rooms of the Academy, while stationed in New York City and its vicinity. While many things had been gathered together beneath this roof, for the benefit and use of the members, yet the central figure in the eyes of many, and certainly in his own eyes, were the library and reading-rooms. In this hall one could meet with distinguished, learned, and skilful men of the profession living in this city, and obtain knowledge and advice from them upon subjects which they might treat of; further, in these rooms one could meet with the great and illustrious dead and the living of the profession of all countries, ready to give information upon all subjects regarding which one might choose to consult them. They were never obtrusive, they were never in a hurry to get away; they would wait one's time with infinite patience.

Basing some remarks upon personal experience in what he facetiously called a "branch" of this library in Washington, the speaker mentioned something which he thought it most desirable a library of this kind should have. The most important thing in a medical library was its collection of journals and file of current journals. Next to these came the collection of statistical matters, hospital reports, society reports, collection of cases, vital statistics. The reason for this was that no physician could by any possibility keep these things in his own library. He would say, speaking roundly, that every physician ought to take five medical journals; that every physician who was a teacher or a specialist, or pretended to keep well up with what was going on in his profession, ought to take a dozen journals; that every journal club and small library should take from twenty-five to fifty journals; that every fairly large library, such as this Academy of Medicine, ought to take three hundred current medical journals, and at least seventy-five transactions; every national collection should take the whole lot, good and bad, which numbered considerably over a thousand journals. This number had to be increased by about thirty thousand, in order to complete the files of back medical journals. While recommending as full a list of medical journals and transactions as possible for consultation purposes, he did not wish to underestimate the value of text-books and bound volumes. In keeping up the files of journals, hospital reports, circulars of the medical schools, etc., a great deal more labor was required than any librarian could attend to. He must have the assistance of a number of skilled men. He had never before so fully appreciated the influence of a large medical journal as when, some months ago, one in this city stated in an editorial that it was out of the line of an editor's work to look up references and all manner of things for its numerous correspondents, and suggested that they devote ten minutes to writing to the library in Washington, offering a reasonable compensation, when it was probable they would get the information they desired. The number of communications which he received the next few weeks, asking for information on special subjects, was overwhelming. It was not in the line of duty of the librarian there to attend to such matters, yet with the aid of three resident physicians, who volunteered their services, the information sought for by the correspondents was given for moderate compensation. Every large medical library must be prepared to meet just such emergencies, and an able corps of assistants was required.

The speaker then referred to the labor involved in getting out the "Index Medicus," a publication which Dr. Andrews had said he looked upon with horror. The speaker thought of it with horror also, but without it what hope could there be, eighty years hence, in attempting to look up matter published to-day?

In concluding, the speaker said he knew it was due to the energy, the tact, and the perseverance of a very few men, members of the Academy, particularly the last three presidents, that success in obtaining this new building had been due, and to them was owed a debt of gratitude by the medical profession all over the world.

Congratulations from Philadelphia.—The PRESIDENT introduced Dr. Weir Mitchell as "the poet, novelist, and distinguished physician."

DR. MITCHELL, on rising, said it would seem his friend Dr. Loomis had prepared his audience for a poem, a novel, and a dose of medicine equally. However, he did not intend to administer any of the three on this occasion. He was himself an honorary member of the Academy, and, therefore, did not come as an entire stranger, but to share in the congratulations of his fellow-fellows, and also to express as a citizen of a

neighboring city warmest interest in the welfare of the Academy. He was reminded, on inquiring for a book in the library, of a visit which he once made to the French Academy in Paris, where he desired to find a certain volume which he knew to be among their accumulated riches. He was utterly unable, however, to find it. This great and learned Academy was very badly housed, and without a catalogue for the best library in the world. When asked why they did not have one, he was told that they were waiting for the government to put up a new building. He was happy to say that things were done differently in this country.

The speaker likened the medical profession to a great guild, and related how, when a stranger in Germany, he was taken sick and was doctored by an unknown physician who, on learning accidentally that his patient was also a physician, refused absolutely to take anything for his services, saying that the year before he had himself been taken care of many weeks while ill in St. Petersburg by a physician and a stranger who declined any compensation. He added: "You, sir, will pay this fee to some other man whom you will take care of in your far country across the sea."

The speaker would say further, that this singular guild possessed a code of morals which was old when Christianity was born, by which we had abided faithfully ever since. It included honor, chastity, brotherhood, and the largest charity. Regarding charity, he added that it had a striking illustration in the fact that men who had attained the highest fame in their profession continued to give from an hour to three hours three or more days of the week to the treatment of the poor after a time when they could hope to reap any reward whatever from such services. This charity in the profession he thought was not fully appreciated by the public, else they would be more generous in their assistance in building halls and libraries.

Dr. Mitchell then referred to the foundation and development of the College of Physicians of Philadelphia, which had the second largest medical library in this country. A library was never large enough as long as a man on going to it could not find what he wanted. A layman had once asked him, why so many books, when most of them contained only matter which had ceased to be of practical use. His reply was that a library was a great museum of facts; it contained matter which must be quoted or referred to by all who wished to write a scientific paper. Let them cease to found libraries and there would soon be a degradation, reducing the profession of medicine to the basis of a useful trade in nostrums.

Congratulations from Boston.—Dr. Reginald H. Fitz, in expressing congratulations from Boston, referred to a branch which might usefully be added to the library of the Academy, namely, a nurse's bureau or directory, like the Nurse's Home, a branch of the academy in Boston which had responded to numerous calls the past year.

The President read letters received from L. L. Seaman, Grover Cleveland, Henry I. Bowditch, N. S. Davis, W. H. Welch, and others.

Dr. Oliver Wendell Holmes wrote: "Academies have been too often thought of as places of honorable retirement, and dignity, and ease; roosts where emeritus professors and effete men of letters, once cocks of the walk, could sit in quiet roost while the fighting, the clucking, and the crowing were going on beneath them. No doubt, to be a member of the French Academy—one of the 'forty immortals'—is an honor worth striving for, in spite of Piron's epigram. But the academy which fulfils its true function is a true working body. It deals with living subjects; it handles unsettled questions; it sets tasks for its members, and furnishes, so far as it can, the appliances required for their prosecution; it offers rewards for meritorious performances, and sits in judgment on the efforts of aspirants for distinction. It furnishes the nearest approach we can expect to a fixed standard of excellence by which the work of new hands and the new work of old hands can be judged. It is a barrier, a breakwater against the rush of false pretensions which are constantly attempting to find their way into public confidence. Nowhere is such a defence more needed than in the sciences and arts which deal with the health of the community. The public is so ready, so eager to be deceived, and the traders in deception are so willing, so hungry to deceive those who will listen to them, that it needs a solid wall of resistance, a close, united phalanx of men of recognized sense, knowledge, and character to stand against them.

"The various forms of what I will venture to christen as pseudopathy and pseudotherapy—though they are known to the public by other names—can never loosen the hold of the intelligent thorough-bred physician on the enlightened members of society so long as the best heads in the profession are banded together in a noble institution like this academy. Only let it ever remain steadfast, unmovable against the recognition of any such pretenders who have no more business in our associations than the astrologist in our observatories or the alchemist in our laboratories.

"We look to this great and able body of men to guard the sacred avenues to the temple of science against all worshippers of idols. The medical profession will always have to fight against the claims of wrong-headed and too-often dishonest individuals and 'schools,' as they call themselves. A fraction of every community will always run after false prophets. There are a certain number of squinting brains, as there are of squinting eyes among every thousand of any population. There will always be a corresponding number of persons calling themselves physicians, ready to make a living out of them. Long may it be before the wholesome barriers are weakened that separate the thoroughbred and truly scientific practitioner from the plausible pretender with his pseudopathy and his pseudotherapy! We trust it will always be enough for a physician to be able to say, 'I am a member of the New York Academy of Medicine.'"

MEDICAL AND CHIRURGICAL STATE FACULTY OF MARYLAND.

Semi-annual Meeting, held at Cambridge, Md., November 11 and 12, 1890.

T. A. Ashby, M.D., President, in the Chair.

Dr. A. H. Bayley, of Cambridge, delivered the address of welcome.

The President's Address.—Dr. T. A. Ashby, after hastily reviewing the early history of the Faculty, its power, its control of the medical profession in this State, and its high authority, spoke of the causes which led to shrinkage of its membership and its loss of authority over the profession. The meetings had always been held in Baltimore. This made it a local society. These semi-annual meetings were started to interest the county members, the fees were reduced, and a large accession of members was the result. The Medical Practice Act was vetoed by the Governor, who was influenced by unprincipled politicians. This was a direct insult to the respectable members of the medical profession of Maryland. Physicians have no lien on an estate, no preference in court. The profession of this State should organize in order to achieve success. This can only be done by this Faculty. To this end local societies should be encouraged in all the counties of the State. Since last year over one hundred members have been added to the Society and the prospects are most encouraging.

Simultaneous Distal Ligation of the Right Common Carotid and Right Subclavian Artery for Supposed Innominate Aneurism. Recovery from the Operation.—Dr. R. Winslow then read a paper on this subject. A dissipated woman had five miscarriages. There was pulsation at the root of right side of the neck at the sterno

clavicular articulation. She was put on low diet, and given iodide of potash, ten grains. Effect not being good, an operation was performed and the subclavian and innominate arteries were ligated at their distal ends. She was kept quiet for some time, and now seems to be well. In such cases, if the aneurism shows no tendency to break, or cause great inconvenience, try postural treatment and the iodides, and postpone operation. He then gave some statistics of similar operations, and the number of aneurisms in age and sex. His operation is not dangerous when done antiseptically, and with an absorbable ligature.

In the discussion which followed DR. R. W. JOHNSON thought in 1871 very few antiseptic operations were performed, and even now surgeons do not always operate antiseptically. It is not a point of election whether you do a distal or a proximal ligation. The strong pulsations of the heart are apt to break through the weakened arterial walls. He also thought that the absorbable ligature was by far the best.

DR. WINSLOW said that most men mentioned were those who operated since antisepsis was introduced, and it was fair to presume that they used it.

Use of Electrolysis in Strieture of the Rectum.—DR. G. T. EARLE then read a paper on this subject. The definition of electrolysis should be exact. A good battery and a reliable milliampèremeter are both indispensable. A Leclanché battery of from thirty to fifty cells is sufficient. A salt solution on the skin increases the electrolytic action. He related several cases in which he used electrodes, gradually increasing in size, and in suspicion of syphilis giving the iodide of potash.

DR. WINSLOW asked if these cases had been under observation long. The cure cannot be maintained too soon after the operation.

DR. W. S. GARDNER referred to one case noted in which an electrode no larger than a match could be introduced, while after a short time Dr. Earle claimed to introduce an electrode one inch in diameter. Was this electrolytic action or simply dilatation?

DR. EARLE said that one case that was operated on two years ago was practically well now. As for the electrode, he said that often an electrode could not be introduced at first, and after the current was turned on it went in easily.

DR. W. P. CHUNN referred to one of the cases mentioned in which Dr. Earle said there was a neoplasm in Douglas's cul-de-sac. This disappeared after treatment. Did he think it was a growth removed by the electricity?

DR. PRESTON said he had not used electricity in this connection, but only in facial blemishes, etc. He thought the idea was only to decompose tissue by a weak current, and not to cauterize it by a strong current as Dr. Earle seemed to do. Some currents are too high.

DR. EARLE said, in reply to Dr. Chunn, that it was not a myoma, but simply an infiltration of tissue around the rectal walls. In reply to Dr. Preston, he said his experience with both weak and strong currents in these cases was that the strong current was decidedly better. These currents do not produce cauterization.

Some Observations on Fibroma of the Nose and Nasopharynx, With a Report of three Cases.—DR. J. K. MERRICK then read a paper on this subject. After defining fibroma and observing that the cause was not evident, in that the negro, who was subject to uterine fibroids, never had nasal fibroma, he drew up a general sketch of the diagnosis and treatment, and then related at length the three cases.

Post-Nasal Obstruction in Children.—DR. JOHN N. MACKENZIE then read a paper on this subject. This is a subject of the utmost importance. It is wonderful that only in the past fifteen years it has been studied. Meyer, of Copenhagen, was the first to introduce it in 1875. He called it adenoid growth of the naso pharynx. The adonæ-adenoma of the vault of the pharnyx is the most common cause. It is generally said that post-nasal obstruction is incompatible with viability of the fœtus. It is most common in children from the fourth to the fifth month. Pliny spoke of it. It grows from the vault of the pharynx as a mass of adenoid tissue, called by the Germans the tissue Luschka, although discovered by Schneider. It begins by a proliferation, then small tumors appear, which may hang down in the pharynx like stalactites or bunches of grapes. The papillomatous form of pharyngeal growth is more frequently met with in this part of the country, while in patients from the West and Lake regions it presents the greatest varieties of growth. In Boston the stalactite variety preponderates. In England he found this very common. The diagnosis is sufficiently easy. It may be confused with a fibroma at the vault of the pharynx, but the treatment is the same. Those who do not make the diagnosis with the rhinoscopic mirror may use the finger. It is like touching an earthworm, and if blood is on the finger when withdrawn, those two facts will confirm the diagnosis. He uses the forceps which bear his name. When a child is brought to him with nasal obstruction or with symptoms of non suppurative otitis media, he introduces these forceps without making a diagnosis and rarely failed to bring away the growth. These growths have a great effect on the child who breathes through his nose; his nose becomes flattened and he has a frog face. This facial expression is characteristic. Meyer, of Copenhagen, uses a "ringomesser," or guillotine knife, introduced through the nose. The best method seems to be the forceps. As a rule he does not use anæsthetics. Occasionally the hemorrhage is very severe.

DR. B. W. GOLDSBOROUGH, in referring to Dr. Merrick's paper, said he had seen one of the patients and she was well.

DR. WILMER BRINTON asked what was the smallest child operated on by Dr. Mackenzie.

DR. MACKENZIE said he did it to those in arms, three or four months. In referring Dr. Merrick's paper, he said the instrument was apt to break, as it had done once in his case. He said he did the operation every day, and at the Johns Hopkins Hospital, in one month, he did it one hundred and seventy times.

DR. S. K. MERRICK said, he used Mackenzie's forceps. In the cases which he could not reach with the forceps, he used his fingers with success.

Prolapse of the Funis.—Dr. Wilmer Brinton read a paper on this subject, in which he related four cases which occurred in a thousand of his.

DR. W. P. CHUNN asked what the hemorrhage was from in Dr. Brinton's cases.

DR. B. W. GOLDBOROUGH said he had a case of this kind. He tried to stop the hemorrhage in vain. Everything failed until he applied turpentine to the fundus of the uterus, and all bleeding stopped.

DR. BRINTON said many people had never seen a case like the one he related. He had seen four, and in one he applied the forceps, and the hemorrhage came from the cervix. He kept tampons on for several hours, and gave ergot. He feels now that the blood does not come from the interior of the uterus. It should be decided what course shall be followed, the very minute the funis presents.

DR. W. S. GARDNER said such cases were very difficult to treat, and needed prompt attention.

Profound Anæmia.—DR. I. C. CLARK, of Federalsburgh, presented a case of profound anæmia. He brought the case for diagnosis. The patient had been an invalid for eight years, and had been under his treatment for the past year without much sign of improvement. The history is very imperfect. His countenance is poor, sight very bad, he complains of muscular weakness and sick stomach, nausea, and occasional vomiting, has a poor appetite, and bowels regular. There has been no improvement for eight years, no better, no worse. He is pale, urine contains no albumin.

DR. WILLIAM OSLER examined this case, and suggested that it was profound anæmia, due to trouble in the large intestine. Such cases often have these retinal changes. The patient was not much emaciated. In these cases iron is not good, but some form of arsenic is better. Cases of pernicious anæmia often fail to improve under iron, and recover under full doses of arsenic.

The Relation of Albuminuria to Puerperal Eclampsia.—DR. W. S. GARDNER then read a paper on this subject, in which he gave the result of an examination of a large number of cases at the Maryland Maternité. Heat and nitric acid were used. His conclusions were: 1. The presence of albumin in the urine of a pregnant woman is not sufficient cause upon which to base a prognosis of probable eclampsia. 2. The failure to find albumin in the urine of a pregnant woman is no evidence of the absence, or at least of the continuance of the absence, of the condition that gives rise to puerperal convulsions. 3. Albumin is so frequently found in considerable quantities in the urine of patients immediately after the appearance of puerperal convulsions that we are justified in making the statement that the convulsions are the probable cause of albuminuria.

DR. BRINTON was much pleased with this paper. He thought if we could collect a large number of cases, much more than presented in this paper, we should be warranted in drawing conclusions as he has done. We cannot always look to the kidney lesion as the cause of death.

DR. G. J. PRESTON thought that some lesion of the central nervous system might cause the trouble.

DR OSLER said that in Montreal he had made the autopsies for ten years, and that in not a single instance were the kidneys in such cases found normal, except one case, which showed an immense cranial hemorrhage, the clot extending from the third to the fourth ventricle of the brain.

DR. GARDNER thinks this experience rather exceptional.

DR. PRESTON asked if the women were systematically examined in each instance.

DR. GARDNER said that the urine was examined in a routine manner in each case, and was done with average care. The object of these urinary examinations was to see if the prognosis of eclampsia could be made before pregnancy.

The Surgical Treatment of Non-pyæmic Abscess of the Liver.—DR. R. W. JOHNSON then read a paper on this subject, with a report of a case, in which he principally advocated aspiration even in the smallest abscesses, as opposed to incision. The aspirator should be used in diagnosis.

DR. R. WINSLOW said that such cases were not so infrequent in this climate as many supposed. All cases he had seen were Germans. He does not agree with Dr. Johnson in the treatment with the aspirator. Small abscesses may be cured by the aspirator. An abscess of the liver should never be allowed to break. It may break inward and cause death.

DR. WM. OSLER said he had seen more abscesses of the liver in the sixteen months that he had been in Baltimore than in five years in Philadelphia. Some abscesses will not get well by aspiration; often they are so low down in the liver that they cannot be found, except by incision. Very often this is due to a multiple pyelo-nephritis. He related a case in which the diagnosis was only made by a laparotomy.

DR. PRESTON also related a case of hepatic abscess, occurring in his practice, and then Dr. Johnson closed the discussion.

Differential Diagnosis in Treatment of Peripheral Neuritis.—DR. GEORGE J. PRESTON read a paper on this subject. He gave the pathology of the disease, its manner of invasion, the symptoms, and said it was often confounded with poliomyelitis in the adult. He related a number of cases occurring in his practice. He thought that it was of more common occurrence than was usually supposed.

DR. WM. OSLER agreed with Dr. Preston in saying that peripheral neuritis was more common than usually supposed. There are often mistakes in the diagnosis, unfortunately. The gait is very characteristic. It is the "steppage" of the French, in which the foot is lifted high to get the toes raised off the ground. This is so characteristic that the diagnosis can be made from it alone. He had seen it after alcoholism, arsenical poisoning, and typhoid fever. It is so much like locomotor ataxia that an unfavorable prognosis is apt to be made. He referred to a case in his own practice in which neuritis was mistaken for ataxia.

Pyoktanin in Eye Diseases.—DR. H. HARLAN then read a paper on this subject. He was led to use pyoktanin from its unusual claims, as given in Merck's *Bulletin*. He thought it impossible for it to do so much. He had given it a very thorough trial, and was more than pleased with it. In some cases nitrate of silver was better.

Injurious Use of Remedies in Eye and Ear Diseases.—DR. H. WOODS then read a paper on this subject, in which he discussed the use of wrong remedies, or strong remedies producing harm. Much of this was done by the general practitioner, who did not want to turn a case over to a specialist.

DR. HARLAN said he had seen such cases as related by Dr. Woods.

Remarks on Vaginal Examinations.—DR. WM. P. CHUNN read a paper on this subject, which gave some very useful hints, and was very well received by the Society.

DR. CHARLES P. NOBLE, of Philadelphia, thought that the touch was often better than the speculum, except in cases of pelvic tumors, malpositions, etc. He spoke of the methods of examination at the patient's home, etc.

Immunity and Protection from Disease.—DR. WM. B. CANFIELD read a paper on this subject, in which he reviewed the latest theories thereon.

After the election of new members and routine business, the Society adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE ANNUAL MEETING AT THE COLLEGE OF SURGEONS—A SUPPOSED CASE OF INDIGENOUS LEPROSY—THE RELATIONSHIP OF THE EYE TO THE CARDIO-VASCULAR SYSTEM—ON ANÆSTHETICS.

LONDON, November 7, 1890.

THE annual meeting at the College of Surgeons took place yesterday, and passed off in much the same manner as previous gatherings of the kind, though it was perhaps more harmonious than some of those which have preceded it. As was the case last year, the President—on this occasion, Mr. Bryant—briefly addressed the fellows and members present. After touching on some of the subjects dealt with in the report of the Council, Mr. Bryant dwelt upon the scientific aim of the College. He said he should omit all controversial subjects, but he exhorted his hearers to remember that their College was dedicated to science of the higher kind, and not to politics; political thought, ways, and action were not always constructive. Mr. Lawson Tait then moved a resolution to the effect that immediate steps should be taken to forward the introduction in Parliament of a bill to amend the constitution of the College, and expressing regret that the Council had as yet shown no disposition to meet the wishes of the fellows and members, in spite of their repeated protests. This resolution was virtually a repetition of that carried at last year's meeting, and it was carried with only six dissentients. In the course of the discussion upon it, Sir Spencer Wells spoke and, while deprecating exciting meetings, suggested that a deputation to the Council was

a more likely means of influencing them. This appeared like holding out a flag of truce on the part of the Council, but any hopes to this effect which the audience might have entertained were speedily dashed to the ground when the President rose and remarked that, although they were extremely pleased to hear Sir Spencer Wells' opinion on the points under discussion, he desired to say that it was only Sir Spencer Wells' opinion, and his hearers must not run away with the idea that it was the opinion of the Council.

At the last meeting of the Pathological Society, Dr. P. S. Abraham narrated a case which had been recently brought under his observation as a supposed example of indigenous leprosy. The patient was a woman of sixty-nine who was greatly emaciated, and whose left arm exhibited a large fungating growth at the region of the elbow. The arm above the elbow was much swollen and œdematous; the skin of the forearm and hand was thick and brawny, scarred in several places, and mottled with dark-brown discoloration. The fingers were flexed; some of the terminal phalanges were gangrenous, and the nails overgrown and clawlike. The terminal phalanx of the little finger had been spontaneously amputated by ulceration. There was some power of movement of the fingers. No well-marked anæsthesia. The rest of the body showed no signs of disease. The patient stated that about thirty years ago she noticed a bean-like growth on the forearm, the surrounding skin became scaly and thick, and this condition gradually extended toward the hand and elbow. The swelling of the limb, however, was comparatively recent, and the cauliflower mass above the elbow had only existed two months. The patient died, and the arm was then examined. No bacilli of leprosy were found. A section of the tumor at the elbow showed it to be a rapidly proliferating epitheliomatous neoplasm. Within the cell-nests, and also between the cells, were some large protoplasmic masses which recalled psorosperms. Sections from a patch on the skin of the arm also indicated commencing epithelioma, as did those taken from the separated ungual phalanx. In some of these, beneath the epidermic increscences, were giant cells surrounded by granulomatous tissue such as could be observed in lupus. This supported Mr. Hutchinson's suggestion that the disease possibly commenced as a superficial lupoid ulceration, scarring over at the spot first attacked, and spreading at the edge, and that the epithelioma had been a secondary development. Dr. Abraham remarked that it was no doubt in great measure owing to the clawed appearance of the hand, the spontaneous loss of one of the phalanges, and the long-continued desquamative condition of the limb, that the idea arose of the case being one of leprosy.

The reading of Dr. Abraham's communication was followed by a short discussion, in the course of which Dr. Colcott Fox remarked that the case appeared to him to be one of tuberculosis with subsequent epithelioma. The lesions of leprosy, he said, were generalized and bilateral. Epithelioma was known to be prone to develop in old lupus scars. Dr. Wilks thought leprosy could not be excluded from the indigenous diseases of this country; he remembered a case which Dr. Addison had described as spurious leprosy, but Sir William Gull had subsequently described it as true leprosy. Mr. Roger Williams said he had never seen any cases of cutaneous epitheliomata like the present specimen.

Myopia and hypermetropia are customarily regarded as being merely ocular defects, and are mostly treated in accordance with this view. At the Harveian Society yesterday evening, however, I heard a very different aspect of the matter presented by Dr. Rayner D. Batten, in a paper of some length. Dr. Batten urged that the errors of refraction just named are not mere local disorders confined to the eye, but that they are the local expressions of changes which involve other organs also. He specially drew attention to the relationship between the eye and the cardio-vascular system, and mentioned some interesting facts bearing on the relationship in question. Thus he said he had never seen a case of optic neuritis in a myope, and, after considerable research, had only been able to find three cases observed by others. He had noticed that atropine given to a hypermetropic patient slowed the pulse instead of quickening it; he attributed this result to its sedative action on the eye, thus removing irritation from the cardio-vascular system. In the operation for internal strabismus severe cardiac depression had been observed to ensue upon the division of the internal rectus—pointing to some association of that muscle with the cardio-vascular system. The cardiac symptoms had been noted to occur either at the moment of dividing the muscle, or when it was placed on the stretch just previous to dividing it.

Dr. Batten related some cases in which errors of refraction were accompanied by cardio-vascular symptoms which were relieved on correcting the refractive errors. He also sketched out, and contrasted, the bodily characteristics of a typical "myope" and "hypermetrope," respectively, and especially in reference to the cardio-vascular system, on which subject he had made numerous observations. He regarded hypermetropia as characteristic of imperfect development; myopia as an example of the opposite. Quoting the remark that a myope did not take exercise because he could not see his way about, he said he would rather say that he did not take exercise because the state of his cardio vascular system was not such as to allow him to do so with comfort to himself. Dr. Batten urged that to correct (by suitable glasses) the errors of refraction in myopic and hypermetropic patients could not be regarded as constituting the whole of the treatment which was desirable, but he did not yet feel able to give definite advice on this subject. We needed to know more about the bodily changes in myopes and hypermetropes, and the diseases to which they were respectively liable.

At the same meeting of the society Mr. Henry Davis read a paper on anæsthetics. Mr. Davis expressed a strong preference for ether in the majority of cases. He first used nitrous oxide to produce anæsthesia, and then gave ether by means of Ormsby's inhaler. He sometimes gave a little chloroform subsequently. Mr. Davis remarked that the experience of Scotch surgeons had prejudiced them strongly in favor of chloroform, but the mortality with it was much higher than with ether. In the discussion on Mr. Davis' paper a pretty unanimous opinion was expressed in favor of ether, with the exceptions that chloroform might be given to young children, or in cases where bronchial trouble existed. One gentleman referred to the A. C. E. mixture, but this was condemned by subsequent speakers. One gentleman said he had been told by American physicians visiting this country that we paid much more attention to the *technique* of anæsthesia than was the case in America, and remarked that he felt much complimented at being told we could do anything better in this country than they could in America. I can, I think, forestall one comment which will rise to the lips of many of your readers on reading this, viz., that in America ether is so generally regarded as a safe anæsthetic, that special attention to the details of its administration is not looked upon as necessary.

THE QUESTION OF PRIORITY—THE POLYCLINIC RESTS ITS CASE.

To the Editor of the Medical Record.

Sir: In your issue of November 15th, Dr. D. B. St. John Roosa writes: "Seven members of the Faculty of the University of the City of New York resigned their positions at that institution on April 4, 1882, for the purpose of founding a Post-Graduate Medical School."

We, the undersigned, during the winter of 1881–82, organized and accepted professorships in the New York

Polyclinic, and opened this school in November, 1882. From the incipiency of the organization it was the expressed intention of its founders to conduct it as a clinical school for practitioners of medicine and surgery.

(Signed) JOHN A. WYETH, M.D.
VIRGIL P. GIBNEY, M.D.
E. GRUENING, M.D.
W. GILL WYLIE, M.D.
LANDON CARTER GRAY, M.D.
A. R. ROBINSON, M.D.

Were they living, the names of Dr. Louis Elsberg and Dr. Richard Brandeis would also be subscribed. The organization of the New York Polyclinic, and its plan of study as carried into practice, were effected, uninfluenced by any similar effort by any other body of men, and while the gentlemen who later on "resigned their positions to organize the New York Post-Graduate School" were teaching in an undergraduate college. The Polyclinic, by the above unimpeachable evidence, was the *pioneer Post-Graduate Medical School in the United States*. On this evidence it rests its case.

Yours truly,
JOHN A. WYETH, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 16 to November 22, 1890.

MOSELEY, EDWARD B., Captain and Assistant Surgeon. Granted leave of absence for one month. S. O. 100, Department of Texas, November 17, 1890.

BURTON, HENRY G., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. S. O. 269, par. 9, Headquarters of the Army, A. G. O., Washington, D. C., November 17, 1890.

PHILLIPS, JOHN L., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, relieved from further duty at Fort Crawford, Col., to take effect on his relinquishing the unexpired portion of his present leave of absence, and will report in person to the commanding officer at Camp Guthrie, Oklahoma Ter., for duty at that station, reporting by letter to the Commanding General, Department of the Missouri. S. O. 269, par. 7, A. G. O., Washington, D. C., November 17, 1890.

JOHNSON, HENRY, Captain and Medical Storekeeper. By direction of the Acting Secretary of War, granted leave of absence from January 1, to March 24, 1891, inclusive, with permission to go beyond sea. S. O. 268, par. 18, A. G. O., Washington, D. C., November 15, 1890.

GANDY, CHARLES M., Captain and Assistant Surgeon, Fort Clark, Tex. By direction of the Acting Secretary of War, granted leave of absence for three months. S. O. 266, par. 10, Headquarters of the Army, A. G. O., Washington, D. C., November 13, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 22, 1890.

AYERS, J. G., Surgeon. Ordered to the Receiving-ship Wabash.

EVANS, SHELDON GUTHRIE. Commissioned an assistant surgeon in the U. S. Navy.

BATES, N. L., Medical Director. Ordered as President of Naval Medical Examining Board, at Mare Island, Cal.

MOORE, A. M., Surgeon. Ordered as member of Naval Medical Examining Board, at Mare Island, Cal.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 22, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	25	7
Scarlet fever	65	10
Cerebro-spinal meningitis	3	3
Measles	141	13
Diphtheria	97	29
Small-pox	1	0
Varicella	5	0
Pertussis	2	0

Value of the Diazo Reaction.—Dr. L. Rütimeyer, who has made between two and three thousand trials of the so-called diazo reaction of urine from 260 patients, declares his belief that it is a very useful guide both in diagnosis and prognosis, being especially valuable in phthisis and typhoid fever. In phthisis he regards it as denoting absorption of caseous matter, and when it is persistent as implying rapid mischief and an early and fatal termination. In cases of general miliary tuberculosis it was always obtained. The number of typhoid cases which were examined was 1,130, of which 87 were fatal. The presence of the reaction is very constant, and it can generally be obtained early. It does not seem to be present in pyrexial intestinal catarrh. If the reaction is not obtained during the first or second week the case, if one of typhoid at all, must be a very slight one. It cannot, however, be affirmed that a well-marked and constant diazo reaction is any sign of a fatal termination, as with phthisis. The reaction is never given by the urine of healthy persons, and was not observed in hysteria, myelitis, hepatitis, diabetes, cystitis, pyelonephritis, benign ovarian cysts, cholelithiasis with jaundice, gastro abdominal catarrh with fever, or in a number of surgical diseases. It was occasionally present in cancer of the stomach and œsophagus, chronic nephritis, caries of bone, cold abscesses, pyæmia, scarlatina, pleurisy with serous effusion, tubercular meningitis, and heart diseases. It was more frequently obtained in croupous pneumonia, actinomycosis of the lung, and malignant diseases of the peritoneum. The method of testing is very simple, two special solutions only being required, a concentrated solution of sulphanilic acid in water and a solution of nitrite of sodium of the strength of 1 in 200. The actual test solution is prepared immediately before use by mixing 200 parts of the sulphanilic acid solution with 10 of pure hydrochloric acid and 6 of the nitrite of sodium solution. This mixture is added to an equal volume of the urine, and sufficient ammonia added to render the whole alkaline. A bright or carmine red coloration denotes the diazo reaction. After from twelve to thirty-six hours a deposit occurs, the upper part of which is green or black. —*The Lancet.*

Dentistry Among the Ancients.—A physician in Rome recently brought to light some interesting specimens of ancient dentistry and artificial teeth in skulls from different Etruscan tombs, dating as far back as the sixth century before Christ.

Carbolic Acid Spray in the Treatment of Hemorrhoids.—Verneuil has obtained very satisfactory results in the treatment of hemorrhoids by spraying the tumors with a spray of carbolic acid. This causes the congestion to disappear rapidly, and also relieves the pain in a very short period of time. The method is not always curative, but it will at least reduce the inflammation to such an extent that it will be possible to examine the parts carefully, and institute such other treatment as may be found necessary.

The Destiny of Congenitally Syphilitic Children.—Hochsinger has followed for some years the careers of 265 children affected with congenital syphilis, and has found that over a third suffered relapses, more than seventy per cent. of these relapses occurring in the first year of life. Among these children, 63 were kept in view for over four years, some for twenty years. Mercurial treatment was adopted in all the cases between the second and the fifteenth month after birth. The 63 cases are thus divided: 1. Ten showed fresh syphilitic appearances within the time specified (over four years), the oldest of these was twelve years of age. 2. Another group comprises 18 who remained healthy in every respect. 3. Finally, the remaining 25 showed no evident signs of syphilis, but some of them have the visible marks of a hereditary infectious disease (small, sunken nose, radiating cicatrices, etc.), and others were affected by a general or undetermined morbid condition (anæmia, debility, etc.). None of the cases showed any direct connection between syphilis and scrofula. As to the forms of the relapses, during the three first years of life the cases showed almost exclusively condylomatous eruptions of the skin and mucous membranes; during the fourth and fifth years gummatous ulcerations or bone disease as well as condylomata; above this age only gummatous changes. Lues laryngis was repeatedly seen between the ages of two and four years, and two of the children (in the third year of life) had hydrocephalus. Severe gummatous destruction was only once seen, in a child eight years of age; in this case the first treatment had begun late (at the age of fifteen months), and had not been thorough. In conclusion, the author thinks the prognosis of congenital syphilis not unfavorable, but largely dependent on the treatment (primary). The earlier mercurial treatment is begun, and the more carefully it is followed out, so much the more certain is a definite cure without relapses. The treatment should continue at least a fortnight after all syphilitic symptoms have ceased. Lingering syphilis in the child's system is shown in another way than by relapses, viz., by lowering the resistance against intercurrent diseases.—*Medical Recorder.*

Phenacetine in Rheumatism.—Dr. Rifat, writing in the *Bulletin Général de Thérapeutique*, November 18, 1890, speaks very hopefully of the use of phenacetine in large doses in the treatment of acute rheumatism, and also of so-called gonorrhœal rheumatism. The remedy was given in doses of sixty to ninety grains a day, and succeeded in curing the disease after all the usual drugs had been tried and abandoned as useless. The number of cases was too small to warrant forming any positive conclusions, but the success in these few instances was so remarkable as to encourage the author to renewed trials.

A Faster in the Seventeenth Century.—Now that Succi, the Italian fasting man, is attracting universal attention, it may be interesting to recall a case of total abstinence from food for forty days, which occurred more than two centuries ago. In the winter of 1684, a certain Isaac Henry Stiphont, of Haarlem, was confined in a lunatic asylum. At this date he was forty years old, and although born of an insane mother had learned a handicraft, married, and conducted himself like other people, until, in the previous autumn, he quarrelled with his brother-in-law, and in a scuffle accidentally broke the man's leg, when the fear of falling into the hands of justice drove him mad. He had been in the asylum a few months when he suddenly took it into his head that he was the Messiah, and resolved to fast forty days and forty nights. Accordingly, on December 6th, he began to abstain from all food, and continued to do so until January 15, 1685. During all this time he took no sustenance whatever; nothing passed his lips but an occasional sip of water for the purpose of cleansing his mouth. If a little broth or brandy was put into the water he discovered the addition instantly, and thrust the cup away untasted. Every effort was made to persuade or compel him to take food. It was even sought to influence him by the pretended apparition of an angel, who brought to him the express command of God that he should eat. He does not appear to have doubted the reality of the visitation, but continued to declare that it was the will of his Heavenly Father that he should fast forty days and forty nights. Stiphont had been a smoker before the commencement of his fast, and continued the daily use of tobacco during the whole time of his abstinence from food. The case had excited great interest, and when the fast was ended the doctors desired the man to take some medicine to stimulate the action of the stomach. He refused, and would only take fish and a special soup to be prepared by his wife. So singular an occurrence made a great noise at the time. Some people ascribed it to a miracle, others to the combined effect of madness and tobacco. A madman, it was said, could endure a temperature that froze his companions, so if insanity made a man impervious to cold, why should it not render him insensible to hunger? Also that the wild hordes of Canada were known, during times of scarcity, to exist for weeks upon water and tobacco, so why should not Stiphont, the civilized, do the same by the help of his madness?—*The Hospital.*

Mr. Thomas Jennings, "the fat man of Tasmania," died on April 1st, at the age of sixty-six. He was 5 feet 10 inches in height, and weighed 561 pounds. His chest measured 68 inches, waist 82, and calf 21½. He was a native of Stream Head, Alberton, Yorkshire.

The Prevention of Conception.—The Detroit Medical and Literary Association recently discussed the question as to the justifiability of preventing conception. Almost every speaker contended that the practice was proper and right, and many said that prevention could be accomplished mechanically without injury to either the man or the woman. There were apparently but few members of the society who opposed this view, or at any rate there were but few who expressed their opposition.

A Point of Comfort.—A small matter which adds greatly to the patient's comfort is the wiping of the lips with the napkin or the handkerchief after liquids or food. It needs some delicacy of perception to do this service acceptably, but when the patient has once known the relief of being anticipated in these little motions he will subsequently notice and resent any forgetfulness or awkwardness in their performance. Remember always that in saving your patient exertion you probably save his strength.—*The Nightingale.*

Pigmentation of Pregnancy.—In general, pigmentation shows itself in pregnant women only upon the face in the form of a chloasma mask, and upon the abdomen along the linea alba. Tarnier, however, has observed a woman at term, who presented upon the chest, thighs, and abdomen disseminated spots of a diameter varying from a ten-cent piece to a quarter-dollar in size. The spots are brown and the intermediary skin paler than normal. The patient had experienced a similar dyschromia in a previous pregnancy, beginning as had this, and ending after delivery.—*Journal of Cutaneous and Venereal Diseases.*

Lacquer Poison.—In China, people, especially foreigners, are not infrequently poisoned by handling newly varnished furniture. The varnish employed is made from the sap of the poison sumach (*Rhus vernicifera*), a bush which in general appearance resembles quite closely the common sumach growing in New England. No effectual remedy has been discovered for this poison, but its severity, and often the intense itching, can be ameliorated by the use externally of lead and opium wash, and in addition of a liniment composed of ten drops of carbolic

acid and twenty of laudanum in an ounce of olive-oil. An important preventive measure, according to Dr. Whitney (*China Medical Missionary Journal*), in cases of newly varnished articles is, after they are well dried, to wipe thoroughly, once a day for two or three days, with a cloth wrung from hot water. This process seems to destroy the poisonous property of the dried varnish, perhaps because the volatile acid is evaporated by the moist heat.

A New Remedy for Phthisis.—In the *China Medical Missionary Journal* for March, 1890, Dr. Lyall writes that he was not long since called to attend a Chinese gentleman for hæmoptysis. The latter informed him that he had heard that human urine was good for consumption, and that for two months he had been taking a wineglassful of his own urine twice daily. He thought that he had put on a good deal of flesh and that his general health was better since he began the treatment.

Congenital Lock-Jaw.—At a recent meeting of the Orthopedic Section of the New York Academy of Medicine, Dr. R. H. Sayre presented a case of congenital trismus. No definite history could be obtained concerning the boy, except that he was five years of age, and that nothing unusual had been noticed about the jaw until a short time ago. The boy was quite intelligent, and no other joints were affected. The jaw appeared to be subluxated backward, and the deformity was presumably congenital. The recession of the jaw, and the apparent atrophy on both sides, added to the interest of the case. Dr. Sayre said that before adopting any operative measures, he would attempt to relieve the case by stretching, and for this purpose would employ a wedge-shaped instrument devised by Dr. L. W. Hubbard, and presented last year before the Society of the Alumni of Bellevue Hospital. It consisted of two plates of steel, fastened together by a separable hinge, and capable of being separated at the other end by turning a screw. Having partly separated the jaws of the instrument, a cork could be inserted between the plates near the hinge, and the action of the screw reversed, when the instrument would exert considerable pressure on the molar teeth.

A Model Nurse.—The editor of our bright little contemporary *Nightingale* has found a nearly perfect nurse in one of the hospitals in this city. After describing some of the preparations being made for the operation, she continues: "The 'operation nurse' was in the meantime vigorously scrubbing her hands and arms. When she turned toward me I noticed that she had on a plain, blue gingham dress. As she wore no pin, I had no further clue to the school of her graduation. The dress cleared the floor by two inches, and a white apron completely covered the skirt of the dress. I next noted that the nurse wore her hair short. Certainly if we all had the strength of mind to cut off our hair we would be, by so much, the better fitted for surgery and, indeed, for all sick-room work. This nurse can thoroughly wash her head every day, or twice or three times a day if she so desires. I next noticed the build of the nurse. She was not tall, but of a firm, compact frame, warranted not to give out. In fact, she officiated at three operations, holding the Sims speculum during two of them, and at the end showed no evidences of fatigue. A word about her arms and hands. Her sleeves were pushed well up above the elbows. Her finger-nails were smooth and clean. The hand was not a white hand. It was reddened by its activities. In a surgical sense, however, it was spotless. I noticed the way in which this nurse performed her duties, how she supplied those hot towels just when they were needed, how alert and noiseless she was, and, at the end of the operation, I watched her carefully counting her sponges. One was missing! I saw her peer here and there and rest not a second until that sponge had been accounted for. I said to myself: 'Here is a nurse who is a credit to us.' Had I a criticism to make, it would refer to a trace of coquetry in the neck arrangement of her dress. It might be added, however, that the nurse was young and pretty and—what could you expect?"

Deafness for High Notes.—Mr. Edwin Cowles, editor of the *Cleveland Leader*, who died last March, had a peculiar form of deafness. He never heard the sound of a bird's note, and until he grew to manhood he always thought the music of the bird was a poetical fiction. "You may fill the room with canary birds," he once said, "and they may all sing at once, and I would never hear a note, but I would hear the fluttering of their wings. I never heard the hissing sound in the human voice; consequently, not knowing of the existence of that sound, I grew up to manhood without ever making it in my speech. A portion of the consonants I never hear, yet I can hear all the vowels. About a quarter of the sounds in the human voice I never hear, and I have to watch the motion of the lips and be governed by the sense of the remarks in order to understand what is said to me. I have walked by the side of a policeman going home at night and seen him blow his whistle, and I never could hear it, although it could be heard by others half a mile away. I never heard the upper notes of the piano, violin, or other musical instruments, although I would hear all the lower notes."—*Cleveland Medical Gazette.*

Sand-bags a Convenience.—The sand-bag is invaluable in the sick room. Get some clean, fine sand, dry it thoroughly in a kettle on the stove. Make a bag about eight inches square of flannel, fill it with dry sand, sew the opening carefully, and cover the bag with cotton or linen. This will prevent the sand from sifting out, and will also enable you to heat the bag quickly by placing it in the oven or even on top of the stove. After once using this you will never again attempt to warm the feet or hands of a sick person with a bottle of hot water or a brick. The sand holds the heat a long time, and the bag can be tucked up to the back without hurting the invalid. It is a good plan to make two or three of the bags and keep them on hand ready for use at any time when needed.—*The Nightingale.*

Summer Drinks.—The *Medical Record* of Calcutta contains some interesting remarks upon the beneficial effects to be derived from non-alcoholic drinks in the height of summer. After remarking that the very bane of European existence in India lies in the habits of eating and drinking, physiological arguments are adduced to show that highly carbonized materials are very deleterious in hot climates. The custom of the Moguls, who for luxury have had no equal in Indian history, is referred to as offering a fitting example. Their drinks consisted of milk, sweetened waters, or sherbets, prepared from subacid fruits, such as lemons, tamarinds, pomegranates, etc., flavored with rose or Keora essences, date juice, numerous vegetable tisanes, and some infusions of glutinous seeds flavored with sugar and essential oils. These were often cooled with ice collected in pits, where it was stored during the winter months. The Oriental races, it is asserted, suffer from few of the diseases which are common to the copious meat-eating, wine-drinking Europeans. For a hot day, a light vegetable diet is recommended, with a spare quantity of meat food and an abundance of cooling, non-alcoholic drinks. Ice is regarded as a necessity, and coffee, tea, and cocoa are to take the place of whiskey-and-soda. The use of aërated waters, prepared from pure and wholesome ingredients, and the admixture in them of the numerous fruit flavorings which abound in the tropics, are regarded with favor, as likely to offer a lucrative source of income to persons engaged in such trade, while also giving the European community a very acceptable form of summer drinks.—*The Lancet.*

THE RHEUMATIC AND GOUTY DIATHESIS AS MANIFESTED IN DISEASES OF THE THROAT.[1]

BY BEVERLEY ROBINSON, M.D.,

NEW YORK.

IN choosing a title for the subject of my paper this evening no one more than I appreciates the difficulties which confront me. In the first place, the literature of the subject is barren in the extreme; in fact, I know of no treatise on this subject. Brief references in classical writers on gout and rheumatism to occasional local inflammations of the throat occurring in the course of these diseases may be found, but that is all. Even scattered articles on this subject are very infrequent.

Unquestionably there are numerous cases in which an acute attack of rheumatism is complicated by a well-marked attack of acute angina, pharyngitis, or laryngitis, but the true nature and significance of the seizure are at first ignored. The inflammatory condition of the throat is merely regarded as a case of ordinary sore-throat or cold, due to the same cause—possibly a wetting—which brought on the rheumatism. Later on, when the rheumatic attack is fully developed, the inflammation of the throat is passed over, or not closely observed, on account of the much greater importance of the joint affection. When we come to examine the matter further, we are forced to admit that there is much that is undetermined about the precise general condition with which we have to do, and in the local changes which appear to be connected with it. The constitutional state indicative of rheumatism and of gout in the throat is only denied by a small number of observers. There are many, however, who think of it in a vague manner who never really attribute much practical importance to it as a factor in the causation of throat disorders. When, however, attention has been directed closely to the influence of these constitutional dyscrasiæ it is no longer possible, in my judgment, to ignore them or diminish their great, though often latent, effect.

It is curious to notice in this connection how different the great foreign medical scholars regard diathesis in the causation of morbid action. The Germans believe many, if not all, throat affections are merely local conditions; the French recognize in numerous instances the underlying arthritism or herpetism. These two morbid expressions are included in one by Professor H. G. Piffard,[2] who unites them in the "rheumatic diathesis" and shows how far-reaching their effects are in the domain of dermatology.

Hardy [3] thus describes those who suffer from this constitutional condition, so far as the skin is concerned: "Their integument is habitually dry and perspiration is diminished. The skin is often the seat of lively itching, even in the absence of eruption. The appetite is generally well developed, and it is well known that the dartrous eat a much larger quantity of food than other patients in analogous conditions. Another important peculiarity is the extreme sensibility of the skin, and the facility with which it is influenced by the lightest and most fugitive impressions; sometimes great excitement, alcoholic excess, watching, use of coffee, of certain kinds of food; sometimes a local excitement, irritating frictions, or the application of a plaster, will give rise to an eruption, often ephemeral and not dartrous in character, but which reveals a particular predisposition of the economy and the existence of a latent vice which needs but a favorable occasion to manifest itself."

To this diathesis, as Piffard writes, Hardy ascribes eczema, lichen, psoriasis, and pityriasis. Now something not unlike this unquestionably exists for the mucous membrane lining the throat. There are individuals in whom the pharynx, fauces, and tonsils are unduly sensitive. The glands of these regions secrete excessively, or very little, upon the slightest pretext. They suffer from localized pains or abnormal sensitiveness in these regions, which have been named neuralgia, hyperæsthesia, paræsthesia, anæsthesia, etc. They are usually well in other respects—so far as can be observed—yet the slightest atmospheric changes, the most ordinary exposures, the smallest departures in diet from a rigid exclusivism, late hours or over-fatigue in any way, inhalations of bad air or a dust-laden atmosphere, will give rise to irritation, discomfort, or soreness of the throat. All this proves the underlying constitutional condition which is present and ever ready to show itself in a more accentuated manner. According to Isambert,[3] many of the cutaneous lesions, and especially the ordinary ones, like eczema, psoriasis, pityriasis, lichen, acne, etc., are accompanied by or alternated with pharyngeal and laryngeal inflammations.

We cannot, it is true, always make out clearly either the same pathological lesion or morphological expression in the throat as we have recognized on the skin. We must, however, be prepared to acknowledge the analogy which exists, and to see in it a fruitful idea for the study and correct interpretation of different forms of sore-throat. Is it possible to recognize in the appearances of the pharyngeal or laryngeal inflammations the nature of the diathesis which occasions them? In reply, we must admit that in many instances this is extremely difficult, not to say impossible. Thus Longstreth says: "The appearances presented by the throat are not characteristic, and dependence on the nature of the occurrence rests on antecedent and concomitant circumstances." [1] Frequently they present all the usual characters belonging to ordinary chronic catarrhal inflammations of the organ affected. They show, however, a disposition to last a much longer time, and also to return with renewed activity, quite frequently.

At times, also, the inflammatory affection of the throat ushers in the rheumatic disease of the joints, and begins in such a way that we may already suspect its nature, if we have met with these cases, by the symptoms described by the patient. A feeling of stiffness of the palate is complained of, which is especially noticeable in talking and in deglutition. This stiffness is apt to affect the muscles of the neck, so that turning the head or neck becomes difficult and painful; sharp pains may run into the

[2] Diseases of the Skin, pp. 124–142.

[3] Leçons théoriques et pratiques sur les Maladies de la Peau, Paris, 1860. Cited by Piffard.

[1] Dartrous is used by Hardy as synonymous with herpetic. Bazin separates this condition into two principal ones, which he names dartre and arthritis.

[2] Annales des Maladies de l'Oreille et du Laryux, vol. i., p. 188 et seq.

[3] Rheumatic Gout and Some Allied Disorders, p. 135. New York, 1882.

eyes, forehead, or ears, if the inflammation extends in either of these directions, and fever may also be present. By and by, as the joint affection develops, the preceding symptoms may fade or disappear entirely. This rheumatic angina has been studied very completely by Lagoanère (1876), who shows that it rarely continues after the rheumatic attack has developed in the joints.

In the affection lately described by Ingals[1] as chronic rheumatic sore-throat, we may have "uncomfortable sensations of pain," with the absence of any distinct physical signs, and merely an existing rheumatic diathesis, but no constitutional symptoms present like fever or rapid pulse. Occasionally, however, there are signs of some value which can be seen with the eye, and which are somewhat characteristic of these constitutional inflammations. Instead of a laryngitis, for example, having a uniform and general redness, we remark that the inflammation is in patches here and there. These patches have different outlines. At times they are mere streaks across the long diameter of the true or false cords. Again they are found as if made with the strokes of a brush near the anterior and posterior commissures of the larynx. These appearances have been insisted upon by Isambert as far back as 1875.[2]

Later on in his paper on lithæmia in the upper air-passages Dr. F. W. Hinkel[3] alludes to a similar condition, which he thus describes: "A patchy congestion of the laryngeal face of the epiglottis, extending along the aryepiglottic folds and over the posterior surface of the ventricular bands."

In addition to this change it is not infrequent to find a marked velvety or slight papillary condition of the interarytenoid commissure, which has been regarded as almost characteristic of laryngeal phthisis. This statement is fortunately not correct, and in a moderate degree at least it is certainly often present in lithæmic conditions and perfectly amenable to judicious local and general medication. In my own experience I have not always found the condition of lithæmia evident in either class of cases. This may have arisen possibly from the fact that the urinary examinations were not made continuously, or with sufficient care or accuracy. Or what seems to me more probable, viz., that some of these cases were instances of incomplete gout and the urine did not reveal the conditions which we ordinarily attribute to lithæmia, because the excess of uric acid was retained in the system and not excreted. In the pharynx the appearances which lead us to suspect the diathetic nature of the disease are the following: The mucous membrane is of a pale rose tint, taking on a somewhat opalescent hue in the naso-pharynx, and particularly around the posterior margin of the septum; the follicles on the mucous membrane are red, large, and prominent, and between them we find numerous large swollen veins; covering the areas of mucous membrane between the follicles, we often notice a quantity of gray, sticky mucus, which harasses the patient and is difficult to expectorate. According to Duckworth,[4] "the pillars of the fauces, especially the posterior pair, the velum, and the uvula, are very red and glazed. They appear as if freshly brushed over with glycerine."

In one instance of gouty granular pharyngitis reported by Guéneau de Mussy[5] the patient expectorated daily masses of carbonate and urate of lime. These came from follicles of the mucous membrane which showed white points.

No doubt this pharyngeal condition may be constantly aggravated by bad hygienic conditions, or by injurious habits, such as pertain to alcoholism or smoking. The result is, that in order to form a judicious appreciation of the cause of the morbid expression in the throat, we must select subjects who are not addicted to these habits, and who likewise are free from the taint of scrofula, syphilis, and tuberculosis. After all, we must fall back in very many cases, in order to make a satisfactory diagnosis, upon the general symptoms offered by the patient. When the underlying dyscrasia is clearly enough of the nature of rheumatism, and when the throat affection is of the nature of a tonsillitis—and especially a follicular tonsillitis—we have some of the following signs to guide us aright. The atmospheric conditions which produce the tonsillitis and cause the rheumatism are similar.

Again, rheumatism and tonsillitis may both be caused by bad drainage. In a large proportion of rheumatic cases attacks of follicular tonsillitis have preceded the outbreak of the rheumatism. In both diseases there are frequent recurrences. Brown,[1] and William Osler have also seen endocarditis complicate tonsillitis. Further, Brown relates the case of a young woman in whom follicular tonsillitis alternated with erythema nodosum, yet the patient never had a rheumatic pain or joint trouble.

The manner in which these cases are connected as regards causation seems to be: 1, Either the rheumatism as a general disease attacks the tonsils, or it may cause inflammation of serous membranes; 2, or the follicles of the tonsils are the gate of entrance for rheumatic poison; 3, or specific germs find an entrance into the body under favorable conditions and then give evidence of their presence by producing inflammation of the tonsils.

In regard to the existence of gout in the throat, while I acknowledge that its existence is often "the last resource of destitute diagnosticians," yet I hold that in its milder forms, at least, its presence is often quite clearly manifest.

Gout should be admitted, I believe, when the following conditions are united: 1. When the local treatment has proven of little or no avail. 2. When during the course of a laryngitis or pharyngitis local irritation and cough suddenly disappear, and one or more of the small joints become affected with a gouty inflammation. 3. When the general treatment appropriate to gout is soon effective in relieving distressing symptoms evidently referable to the throat.

In an interesting article on "Gout in the Throat," Dr. Morell Mackenzie[2] affirms that, in the course of a long and somewhat large experience, he has met with a few cases, but does not consider that gout is by any means common in the throat. This opinion is shared by many. Most of the cases of "gouty sore-throat" which have been described are in some manner connected with metastasis. Thus, for example, if pain, irritation, or inflammation is aroused in the pharynx or larynx very soon after a gouty development has disappeared elsewhere, the throat is known to be gouty. Harrison Allen[3] has thought that the study of sore-throat as it occurs in gouty subjects, independent of metastasis, and which yields only to antigouty remedies, might prove of interest, and reports several cases of this kind. According to him, the distress in the throat is not apt to occur in acute attacks of gout, but rather in those persons who are prone to neuralgic attacks of an irregular form. Frequently it occurs after indiscretions of diet, and is often preceded by dyspepsia, constipation, and a persistently furred tongue. The phenomena of the gouty condition are, as we know, infinitely varied in type and at times very peculiar. According to Jonathan Hutchinson[4] many of them are caused by local restricted attacks of peripheral neuritis. If this be true, I can explain satisfactorily many of those cases in which there is painful deglutition or a steady localized ache in certain limited areas of the tonsillar or laryngeal region, which I have frequently met with, and which resist all sorts of local treatment, and finally only yield to treatment by alkalies or colchicum and restricted diet.

It must always be borne in mind that every case of sore-throat which occurs in a gouty subject is not of necessity gouty. A patient, as Dr. Mackenzie says, may be attacked with a septic pneumonia or with cardiac disease, just as he may break his leg or cut his finger, and it must not be inferred that these diseases necessarily have anything to do with a gouty dyscrasia. The only disease with which the sore-throat of gout can be confounded is the irritable throat of lithæmia. The latter occurs in young persons and is amenable to abstention from wine and too much nitrogenous food, with the additional aid of a brisk purgative. The lithæmic throat is usually uniformly red, the tonsils are slightly swollen, the uvula elongated and thickened, and all these parts bathed with a considerable amount of mucous secretion. Rarely is there any acute pain in the throat, and if there be any discomfort of this organ it is more in the pharynx than in the tonsils.[1] True lithæmia is quite distinct from gout. In the former case the urine is heavy, loaded with lithates, and small in quantity, while in the true gouty cases the urine is usually clear, abundant, and contains a small quantity, relatively, of urates or of uric acid (Garrod).

One peculiarity which affects equally the lithæmic as well as the real gouty throat (Allen) is the fact that applications of a stimulant or astringent nature, instead of affording marked relief to the patient, are apt to cause additional distress. As it is often a very nice question to make a positive diagnosis of the gouty condition before regular treatment has been instituted, and in the absence of facts in the personal history which enable us to affirm it, any conditions which, being present, point strongly in that direction have considerable importance. Allen considers that the best guides, perhaps, to a gouty condition are furnished by the permanent teeth. The peculiar features remarked in them are that the incisors are large, thick in the antero-posterior diameter, and the enamel yellow. The free margins are blunt, without serrations, and sometimes very much worn, so as to resemble pegs rather than edge-cutting instruments (Fothergill). The gums show a tendency to recede from the neck of the tooth. A point of considerable importance in this connection may be noted in the point of departure of the lesion. For other diathetic conditions this seems to be marked. In syphilis it is the soft palate, in scrofula the pharynx, in tuberculosis the larynx, in rheumatism and gout it is the tongue (Isambert). In this organ we can notice frequently certain well-defined lesions which, if present, throw considerable light upon the nature of the throat trouble. The tongue may be simply covered with a yellowish coating with a more or less defined sinuous outline. This coating may be confounded at first with that due to a passing bilious condition, or to the habit of smoking or chewing. But when these habits do not exist, and when the signs of disturbed digestion are not present, we are disposed to regard it as an arthritic evidence. In more advanced conditions the tongue is more or less deeply furrowed, either on the middle of its dorsal surface or along its margin. This condition might be confounded with the appearances often met with in syphilis or tuberculosis. In syphilis, however, we find inflammation and thickening of the substance around the ulcer, besides the general symptoms which show its presence. In tuberculosis the ulcerations are rounder and deeper, and we are apt to get a history of phthisis and to discover evidences in the lungs of its existence. Those dry white patches on the tongue which resemble the eschar produced by the local action of nitrate of silver, and which have been called psoriasis of the tongue, are occasionally present at the same time with the pharyngo-laryngeal inflammation which seemingly should be attached to the herpetic or arthritic diathesis.

These different lingual appearances have been designated by similar names to cutaneous affections of a more or less analogous type which may exist at the same time that they are present. Thus we read of lingual pityriasis, eczema, psoriasis, etc. The latter term is the only one which I should be willing to accept as being justified by any morphological resemblance between the lesions of the cutaneous and mucous surfaces. As regards attaching the definite lingual aspects more to certain degrees, or kinds of pharyngo laryngeal inflammations than to others, this appears to me in general extremely difficult, and I have not been able hitherto to establish in my own experience very evident distinctions.

What is the nature of the underlying dyscrasia which occasions these inflammatory conditions of the throat as well as the concomitant eruptions of the skin which so frequently are present? Many different theories have been offered to explain it. Among these I would select that of Bence Jones [2] as being on the whole the most satisfactory, since it embraces a wider range of facts than any other, and seems to solve tolerably well in my mind the numerous problems as they are clinically observed.[2] This theory is that of suboxidation. By suboxidation we mean that the substances taken into the stomach as food are not sufficiently metamorphosed into completely soluble substances in the blood and tissues, and accumulate in the economy to that degree that they occasion morbid effects. Uric, lactic, and oxalic acid, creatin, creatinin, etc., are the chief products of imperfect oxidation. Why do these substances accumulate in the economy? In some instances it is because the amount of food taken is more than sufficient for the needs of the body, and instead of it being thoroughly oxidized, or reduced to a soluble form and eliminated, it remains in an insoluble state and is partly retained in the blood. Frequently the quantity and quality of the food taken are as they should be, but the power of oxidation is insufficient, or the quantity of this element is diminished. The latter condition we meet with in anæmia of different forms and many states of lowered vitality. The small power of oxidation may be inherited or acquired, and the precise cause of it is more than difficult accurately to determine. All that we can do at times is to combat the results and not the etiology of this lack of power. The special organ which is most at fault in many of the instances where suboxidation is at the bottom of the actual disorder is the liver.

The liver is not always diseased in such cases, but it is functionally inactive and requires constant stimulation. In this phase of suboxidation, and owing to the accumulation of the different organic acids, the blood is rendered subalkaline and this subalkalinity prevents, as we are aware, the processes of oxidation from being as completely carried on. Whenever there is an accumulation of suboxidized materials in the blood and tissues, unless the kidneys are equal to carrying them off from, or out of, the economy, we turn to the bowels as the real efficient emunctory of the body. From the frequent appeals that are made to the bowels, both by nature and man, this organ does not, as a rule, suffer much from becoming the way of exit for an excessive amount of excrementitious substances. Unfortunately, however, other vicarious avenues are also selected for the passage outward of the pent-up *materies peccans* which indicates the diathetic condition, and hence it is that the skin and mucous membrane of the throat often show evidence of irritation and disease as a consequence of this selection. No doubt, therefore, the same, or very analogous, conditions of the body produce on different occasions painful affections of the joints (arthritism), eruptions of the skin (herpetism, dartre, rheumatism), or inflammatory diseases of the throat. I grant that it is not always easy, or even possible, to give a clear and irrefutable demonstration of this fact, but in many cases, if we weigh carefully the evidence we possess, we must admit that it is the only rational

[1] A masterly description of The Nervous Symptoms of Lithæmia, by J. M. Da Costa, M.D., may be read in the American Journal of the Medical Sciences for October, 1881.

[1] Lectures on Some of the Applications of Chemistry and Mechanics to Pathology and Therapeutics. London, 1867.

[2] I am glad to find that Dr. William H. Draper (v. Pepper's System of Medicine, vol. ii., p. 113) writes that "the purely chemical theory of gout has much to commend it," etc.

method of uniting many isolated examples which between them manifest a long list of close relationships.

The late Dr Murchison regarded gout merely as a result or variety of lithæmia. "This latter condition of the blood," says Duckworth,[1] "is recognized on all hands as due to imperfect digestion and functional derangement of the liver." Piffard also regards deficient functional activity of the liver as being the *fons et origo* of most of the disorders from suboxidation.[2]

I have been led to believe that many throat disorders which are called rheumatic, or gouty, may be very properly included in this list. The prognosis in the foregoing cases is always good. Frequently the symptoms fade away in the other signs of acute articular rheumatism which rapidly become manifest. In that case the development of the articular symptoms merely shows distinctly the nature of the throat affection which has preceded them. In the rheumatic sore-throat which takes place when the health is not otherwise impaired, and in which the patient complains mainly of a pain over the hyoid bone, larynx, or tonsils, the trouble may persist a long while without appreciable relief, even from what appear to be appropriate remedies. Ultimately, however, these patients recover, and I have never known any real gravity to attach to them. I should, perhaps, make an exception in this place for certain cases of enlarged lingual tonsils, apparently of rheumatic or gouty origin, which have occasioned in my experience very distressing symptoms at times. These symptoms are sensation of constriction around the throat, choking attacks, disability in swallowing, and marked dysphonia. On one occasion I treated a lady who suffered from the formation of an abscess in this region apparently, and in whom, previous to the bursting of the abscess, the symptoms were extremely painful and also quite alarming, as the patient seemed to dread asphyxia from choking—and there was sufficient ground for her natural fears. In medical literature there are some instances which seem to indicate the possible gravity of some of these cases, notably in the case of gout.

Barthez [3] reports, after Musgraves, that in one instance an attack of metastatic gout in the throat was sufficiently severe to threaten suffocation and necessitate a tracheotomy in order to save life.

In chronic gout Virchow has made a study of the deposits which are occasionally formed around the laryngeal cartilages. Sir Morell Mackenzie, in his four typical cases of gout in the throat, mentions acute œdema of the uvula, which disappeared suddenly when an ordinary attack of gout developed, and fungous ulceration of the left ventricular band which was very like cancer.

Isambert cites cases of nervous dysphonia due to incomplete paralysis of the adductor muscles of the larynx, and which he attaches to the same conditions which produce cutaneous eruptions and a deposit of uric acid in the urine. This same observer is inclined to the belief, from his observations, and those of Bazin, that a laryngitis of gouty nature may ultimately be changed into a true cancerous affection, and he refers to cases which corroborate this view. Is there a rational basis for the treatment of these cases? Certainly there is, if we refer to the nature of these affections as far as I have been able to determine it, and if we recognize the indications already given. In the first place, the blood is subalkaline from retention of the excrementitious substances which should normally be expelled. In the second place, the aliments taken as food are not properly oxidized and do not therefore take forms like urea, which are soluble and easily eliminated. As Piffard remarks, there are two objects which should constantly be held in view: 1, The depuration of the blood; 2, the increased oxidation of alimentary substances introduced into the stomach. The first object should be attained by the use of alkaline diuretics, by purgatives, by increasing elimination through the skin, which can be accomplished by exercise, baths, friction. The second object must be attained by the use of iron, oxygen—breathing fresh, pure air.

Among the alkaline diuretics I believe natural Vichy water to be one of the best. It promotes the flow of urine, it reduces the subalkalinity of the blood. Among the purgatives—and particularly for the reason that the liver is probably the organ most at fault—I recommend repeated small doses of calomel, podophyllin, or Carlsbad Sprudel salts, dissolved in warm water, or in the Sprudel water itself. Whatever theory we may believe in regarding these therapeutic agents, there is little doubt in my mind that in very many cases after their use the quantity of bile evacuated in the stools, and the quantity of uric acid and urea eliminated by the urine is often notably increased. I confess that there are cases in which the precise result of the hepatic stimulant is not evident. I also am obliged to say that occasionally we meet with cases of undoubted rheumatic or gouty sore-throat where all purgative medicines—even the most appropriate—seem to be wholly without good effect. These are, I believe, instances in which the liver is not primarily at fault. Under these circumstances I am often impressed with the fact of the great benefit received from frequently repeated Turkish baths, when they are judiciously given. The skin is thus made to act more thoroughly, and if we may form correct conclusions from the results obtained it is obvious that the skin must be the organ most in need of attention. Exercise and friction—meaning by that walking, riding, tennis playing—combined with massage and passive movements, are powerful adjuncts to the usefulness of the Turkish bath.

As the main carrier of oxygen to the economy is the blood, iron should be given in small doses and during long periods of time, to increase the oxidizing power of the economy. In my experience no preparation of iron for this purpose equals the tincture of the chloride of iron in ten to twenty drop doses, three or four times in twenty four hours. I also believe that inhalations of pure oxygen, or oxygen gas in which there is a certain proportion of nitrogen, help the patient surely and continuously by enabling him to assimilate some of the iron he is taking, which without the oxygen gas would have no appreciable good effect whatever. Of course the diet should be regulated, and if the patient be taking daily an excess of albuminoid or starchy food, it should be diminished in proportion to the needs of the economy, or to the ability to consume thoroughly the food that is given him. Now, in my judgment, the quantity of food required by some people to preserve and keep in good condition the bodily nutrition differs a very great deal from the amount necessary with others, and no hard-and-fast rules should be laid down in regard to quantity of food. The main thing is to insure perfect digestion and assimilation of what is actually taken, and this I believe is accomplished by consulting somewhat the individual peculiarities we have to do with, and by inculcating rigid observance of sobriety in all things pertaining to food and drink. While, however, I believe the foregoing general rules should govern dietary requirements I am not averse to being inflexible in forbidding any but the most limited indulgence in sweets in any form, or in the use of farinaceous food, particularly in cases where it causes fermentative dyspepsia and all the evils which proceed therefrom. In some of these cases I am confident that I have obtained excellent modifying effects from the exhibition of arsenic, either in the form of arsenious acid, Pearson's or Fowler's solution, or, what is still more useful, the natural mineral water of Bourboule.

The internal use of the French sulphur waters, and especially those of Aix-les-Bains,[4] in Savoy, have unquestionably benefited some of my patients in a remarkable

[1] Loc. cit., p. 11.

[4] Journal of Laryngology, August, 1889.

[4] A distinguished physician of New York informs me that the waters of Marlioz and Challes (resorts near Aix), are more frequently drunk by patients than those of Aix-les-Bains.

manner. In regard to our own sulphur springs, and notably those of Sharon and Richfield, I have latterly spoken against their utility when drunk in any great quantity. Owing, apparently, to the large proportion of insoluble salts of lime which enter into their composition, they prove indigestible, and instead of being active agents in eliminating gouty products from the economy, are apt to cause their retention. I have undoubtedly seen gouty patients who have returned from a season at Richfield with further pain and stiffening of the joints, and with aching and hardening of the muscles of the limbs. So far, however, as the gouty nature of the throat trouble is concerned, I know of no remedy that at times clears up the situation to the same degree that colchicum, or its alkaloid colchicine, does. Many patients, in my experience, upon whom I have tried everything I could think of that seemed in any way rational or indicated, or who have simply remained in a stationary condition or become greater sufferers, have been, in one week's time from the period of beginning to take this drug, so much improved generally and locally that they have expressed themselves as feeling like new beings. The urine would occasionally give evidence of this treatment by containing a large amount of urates and of uric acid. Not infrequently it would remain wholly negative. In these and other cases "the drug probably acts in more ways than one, possessing not only specific anodyne properties, due, perhaps, largely to its action as a vascular depressant, but also the power of hastening and modifying hepatic and other tissue-metabolism, together with an eliminant property." [1]

So much for the general treatment of these cases. How shall they be treated locally? Those who have written with, as I believe, accurate and extensive knowledge of the subject have claimed that astringent applications to the throat are not merely useless but frequently harmful. They do not alter advantageously redness and irritability of the mucous membrane. They do not produce secondary quieting and soothing effects, such as we often observe after the treatment in this manner of localized inflammatory affections, non-diathetic in character. On the contrary, they augment and aggravate the local congestion or thickening, and the patients soon become tired and restive under the repeated application of a treatment from which they experience little or no relief. The foregoing statements are, without doubt, true in many cases. And yet, as always in medicine, there are exceptions to the rule, and I find occasionally rheumatic and gouty individuals whose throats are notably benefited by applications of iodine, zinc, iron, etc. It is not inappropriate in some of these irritable throats to follow the application of the astringent by the use of an anodyne, like the tincture of opium, or to combine the opiate with the astringent, and make the double application at the same time. As a rule, however, the soothing sprays or inhalations are the ones from which we derive most benefit. Different modifications of alkaline sprays with carbolic acid, thymol, menthol in small proportions, and more or less glycerine, are what I have usually found most effective. Where the nervous irritation and sensibility are very great, cocaine in small quantity may occasionally be added with some benefit. Warm inhalations of steam impregnated with benzoin and fir wood oil, or eucalyptol, are soothing and helpful at bedtime, but should not be tried during the day, as they will tend to increase congestion and sensitiveness, on account of the atmospheric changes to which the patient is of necessity exposed. It is in these cases that we obtain our most satisfactory results from the inhalations and pulverizations as employed at the sulphur spas in Europe, and now, I am happy to state, in two places at least in the United States, of general resort, namely, Sharon and Richfield Springs. At Sharon it has been found, in certain cases, that the sulphur water, combined with pine needle extract, is even more useful than the sulphur water alone. Where the general condition of the patient is poor and requires strengthening, the sulphur baths, given twice a week, or every other day, are valuable as a corroborant; but I do not believe they have any but this indirect influence in ameliorating the inflamed mucous surfaces. The air of the country of, or about, the sulphur springs, I have thought, may be especially useful, but with respect to this judgment I advance it as merely having probabilities in its support.

PERSONAL EXPERIENCE WITH GALL-STONES, AND THE OPERATION FOR THEIR RELIEF.[1]

By WILLIAM WOTKYNS SEYMOUR, A.B. Yale, M.D. Harvard,

TROY, N. Y.

FORMERLY HOUSE SURGEON OF THE BOSTON CITY HOSPITAL; MEMBER OF THE AMERICAN MEDICAL ASSOCIATION; FELLOW OF THE NEW YORK STATE MEDICAL ASSOCIATION; FELLOW OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS; MEMBER OF THE BRITISH MEDICAL ASSOCIATION; PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF VERMONT.

Quæ quæ missèrima vidi,
Et quorum pars magna fui.—VIRG., ii., 5.

My reasons for presenting a paper on this subject are the quite unique experiences I have had with the disease as attendant, operator, and patient, and the very pronounced views I entertain regarding cholecystotomy which I have successfully undergone at the hands of Mr. Tait. From when I first read of Mr. Tait's work, and considered its aims, I was a firm believer in the propriety of the operation. During the first few years of my practice I made at least seven autopsies, in which cancer of the liver and gall-bladder appeared to be secondary to gall-stone attacks occurring over years. So firm was I in the conviction that in obstinately recurring attacks operation was the only cure that I advised it in numerous cases, and it was as uniformly declined by patients or attendants, and I was regarded as having the operation mania. However, in 1885, I was asked to see a woman, fifty-four years of age, Irish, and a widow, who for eighteen months had suffered the torments of the damned during the attendance of many physicians. Three months before my first visit she had passed, after terrible pain, three gall-stones the size of beech-nuts, and from that time out was in constant torment with pain, nausea, and vomiting. I found her with a temperature a couple of degrees above normal, extremely emaciated, and of an old-gold color. I told her that she had gall stones, and might have as complications malignant disease and occlusion of the common duct, and advised, as the only hope, operation. After a wonderfully cool weighing of the subject she desired me to operate. This I did eleven days later, at which time she had become a tea green color. On opening the abdomen I found the gall-bladder empty, but there was marked evidence of malignant disease in the liver, and I therefore closed the wound. Five weeks later I told the patient what I had found, and she bade me make, when she died, a thorough autopsy, and to invite my assistants and all who might be interested. When she died, eight and a half weeks after the operation, I found plastic occlusion of the common duct, a cancerous nodule pressing upon the junction of the cystic and hepatic ducts, and twenty-six gall-stones, weighing half an ounce Troy, in the hepatic duct and its branches, which latter were dilated to the size of a centimetre and filled with yellowish matter. To my mind it was evident that the injury done by the passage of the three gall-stones, three months before operation, had led to the plastic occlusion of the common duct, and that the existence of cancer was to be explained by the prolonged irritation of gall-stones.

The next year I myself became a victim of the disease, and the increasing frequency of the attacks led me to consider, from a personal stand-point, the desirability of

[1] Read at the meeting of the American Association of Obstetricians and Gynecologists, Philadelphia, September 18, 1890.

operative interference. It was a subject in which my life and the future of my family was involved, and not many hours, certainly not a day, passed in which I did not review the propriety of operative interference, only to become more and more convinced of its being the only certain relief, if not cure. However, there were some things which led me to defer operation, and on November 27, 1888, I was asked to see Mrs. K ——, fifty-six years of age, who had been a patient of Dr. C. E. Nichols, of Troy. Five weeks before I first saw her the patient began to have some pain in the right side and to become jaundiced. The pain was never acute. Dr. Nichols diagnosticated an enlargement of the liver, and said it was probably malignant. Professor Van der Veer saw her in consultation with Dr. Nichols three weeks later, and advised, he tells me, an exploration, unless there was speedy improvement. To this Dr. Nichols was extremely opposed, assuring the family that the case was cancerous and an operation would be fatal. On November 27th I was asked to take charge of the case, and found the patient markedly emaciated, with intense jaundice, anorexia, constant vomiting, putty-colored stools, constant, but not acute, pain in the hepatic region, full pulse of 58 to 65, and temperature of 100° F. Physical examination showed no ascites and no enlargement of the liver, but its whole lower border was very tender, and the gall-bladder, which I could readily feel, intensely so. My diagnosis was gall-stones, and I advised an immediate operation as the only hope, as each day the patient was losing ground. This met with opposition on the part of the family, which opposition was encouraged by the previous attendant. During the eighteen days which elapsed before consent could be had for an operation, the nausea, vomiting, and pain continued, and the failure of strength was so apparent that finally even the family recognized the necessity of an operation if she was to be saved. The temperature during these eighteen days had varied from 98.6° to 101.5° F., and the pulse from 65 to 90.

On December 15th, at 1 P.M., I operated, with the assistance of Drs. Bontecou, Hutchison, and Gordinier, and sulphuric ether was the anæsthetic. A vertical incision was made over the enlarged gall-bladder, and on opening the belly the omentum was found adherent to the whole lower border of the liver. In carefully breaking up these adhesions over the distended gall-bladder I opened an abscess containing a couple of ounces of pus, and lying between the upper surface of the gall-bladder and the liver. In the pus there was a gall-stone three-eighths of an inch in diameter. After thoroughly irrigating the abscess cavity I laid open the fundus of the gall-bladder up to the opening through which the stone had ulcerated, and I found the gall-bladder packed with the stones I now show you, numbering one hundred and fifteen, and weighing two ounces Troy. The stones were so wedged that I found considerable difficulty in removing them until I had broken up their union with a strong jet of water. This jet, a sort of placer mining, worked admirably, and I speedily had the satisfaction to find all thoroughly removed. Owing to the fear that some of the pus might have escaped into the belly, I washed out the abdomen thoroughly through the original wound, and then made a suprapubic counter-opening and flushed the abdomen again freely with hot water. A glass drainage-tube was inserted into the lower wound, and I then proceeded to stitch the gall bladder to the abdominal wound with sutures of silk. In doing this the left side of the gall-bladder was torn, obliging me to close the tear with several Lembert sutures of iron-dyed silk, and to make the tear still more secure I stitched to the gall bladder a piece of the omentum, which appeared to reinforce it strongly. A rubber drainage-tube was introduced into the gall-bladder and the wound closed with silkworm-gut. The operation lasted one hour. Apart from some nausea produced by the ether the patient had very little discomfort from the operation. The same evening the temperature, pulse, and respiration (which before operation were 101.5° F.; pulse, 65; respiration, 26) were normal, pulse, 104, respiration, 24. At four the same afternoon urine was passed voluntarily, and some flatus. No food was given by the mouth the first twenty-four hours. The day after the operation urine, flatus, and a putty-colored stool were passed. No pain, nausea, or vomiting; bile saturated the dressings, requiring frequent change of them. The measured quantity of bile was about eighteen ounces in one twenty-four hours. From this time, for three days, her condition was encouraging, for although the pulse remained from 114 to 120, and temperature from 102 to 98° F., yet she took nourishment, slept, had no pain or tympanites, the urine cleared up, and she expressed herself as markedly better.

On the morning of the 19th she had an offensive bilious movement; the temperature fell to 98°, and the belly was flat; and at 3 P.M. temperature was 98.4° F.; pulse, 94; and respiration, 22. I thought she was sure to recover, but at 10 P.M. she suddenly went into a collapse, and died, in spite of all I could do, at 5 A.M. on the 20th. The autopsy showed no peritonitis, no malignant disease; the sutures were intact, the adhesions firm, and the ducts patent. The death must be charged to cholæmia and delay. I think I can truly say delaying operation killed her.

The next case is my own. I have always been athletic, and as a medical student won the heavy weight sparring championship of Harvard; am five feet nine inches in height, weigh two hundred and ten pounds, and am thirty-seven years of age. The first symptom which I now associate with my trouble was an attack of atrocious pain in the epigastrium, six years ago, coming on suddenly while I was in the field shooting. The pain was simply horrible; I could scarcely breathe, was bathed in a cold sweat, and found I could run easier than I could walk. By several rapid bursts of running I reached, more dead than alive, the house where I was staying, a hundred rods distant. My wife and family were alarmed at my ghastly color and thought me dangerously ill. However, a full dose of morphia and atropia, hypodermatically, gave me relief in twenty minutes, and in a couple of hours I was again in the fields. I had no further trouble save an occasional attack of what I regarded as indigestion, until four years ago, when I had a very severe attack, ushered in by terrific pain and vomiting. The illness lasted ten days, and jaundice came on almost immediately, and persisted for some time after I had taken up my work. My attacks became more and more frequent, but were not accompanied by jaundice. As they increased in frequency my attention was drawn more closely to their various symptoms, particularly as in the subsequent attacks, owing to the absence of jaundice, doubt was cast by my friends on my diagnosis of gall-stones. The attacks were usually sudden, having no connection with the taking of food, only rarely accompanied by vomiting, always by clay-colored stools, and later in my case I noticed that clay-colored stools would sometimes precede an attack by one, two, or three days. The pain was always in the epigastrium, never in the liver or gall-bladder, and there never was any shoulder pain. This shoulder pain has, in my experience, occurred in but an extremely small proportion of cases. Usually my attacks were of short duration, consisting of one or two paroxysms, which were relieved by $\frac{1}{3}$ grain of morphia and one to $\frac{1}{100}$ grains of atropia. I ought to say that I am very sensitive to morphia and especially so to atropia. In the early spring of 1889 my attacks became much more frequent; probably due to driving over as bad city streets and roads as are to be found; the attacks not infrequently coming on at night, awakening me from sleep by a sense of uneasiness and tension in the epigastrium. Associated with this epigastric uneasiness there was no tenderness in the epigastrium; although palpation always showed tenderness of the lower border of the liver it was exquisite over the gall bladder. Many a time after

being so awakened I have for a long time studied the augmenting violence of these paroxysms, and noted by palpation the increasing tenderness of liver and gall-bladder, until hellish pain banished scientific curiosity and I sought relief in morphia. Later in the summer of 1889 I had several paroxysms a week, but none were so severe as to keep me from my daily round, although often I would be compelled to lie down in a patient's house, or, with set teeth, finish my visit to return home to get into a hot bath for relief rather than to be constantly resorting to morphia. The evening I left Albany to attend our Cincinnati meeting I had two paroxysms, brought on by the shaking of the train, and each day after I had at least one, and often several paroxysms. In Chicago I was obliged several times to cut short carriage drives because of the pain even an easy carriage brought on. So constant were the attacks, so great was the pain, and so hopeless the future without operation, that I wrote from Chicago to Mr. Tait asking if he would operate on me. On my return home I took up my work, but found that the slight motion of an easy buck-board over a smooth road would bring on pain in a few minutes. This I combated with grit, hot baths, wild yam, and when I could bear it no longer, morphia. Three weeks of trying, wearing work went by when I received Mr. Tait's reply to my Chicago letter. It was, "Come over and I will do my best for you." In a week I made my preparations, and on November 30th my wife and I sailed on the City of Paris. Every day at sea I had one or more attacks which yielded to morphia. I felt that if I was to be operated on, as I intended to be, I should at least enjoy all the comfort morphia could give. It was December 11th before I could see Mr. Tait, who was absent from home on my arrival. He looked me over; could find no enlargement of the liver, no jaundice, and the only evidence of gall-stones, apart from my history, was exquisite tenderness over the gall-bladder. I had had, by the way, a tremendous attack forty-eight hours before. In view of my history, he thought I ought to be operated on, and I asked him to operate the next day, so as to relieve my wife and friends on this side from their anxiety. Mr. Tait counselled a few days' delay, advising me to get my lodgings, and as soon as settled he would send me a nurse and operate a few days later. The same day I obtained excellent lodgings and found awaiting me the nurse who was to care for me. The day but one after Mr. Tait operated. A mixture of ether and chloroform (two to one) was used in a Clover's inhaler.

The operation was, I am told, a very difficult one, because of the great thickness of the abdominal walls, and the fact that I had a contracted gall-bladder so small as to make its attachment to the abdominal walls very difficult. In addition to a large quantity of grit, Mr. Tait removed one hundred and fourteen stones, which are contained in the vials B and C. There was sharp hemorrhage from a branch of the cystic artery, which caused some annoyance. A rubber drainage-tube was inserted into the gall-bladder, which was united to the abdominal wall by four silk sutures, and then a rubber drainage-tube was inserted, and the abdominal wound closed with four silk sutures. The duration of the operation was fifteen minutes. The only discomfort after the operation was from the dragging of the gall-bladder in the wound and the laryngeal irritation produced by the ether. For thirty hours I had no nourishment, and after that a teaspoonful every fifteen minutes of equal parts of milk and lime-water. The fourth day my bowels were moved by a turpentine enema, and on the fifth day, owing to some hemorrhage, the drainage-tube and stitches were removed, and I could turn to either side, much to my relief. I sat up the ninth day, went out to dinner the tenth, and walked four miles the twelfth day. I had determined to be operated on before my constitution broke under the torture, and I think my prompt recovery proved the wisdom of so doing. For the first few days after the operation the dressings were saturated with bile and required changing every fifteen minutes to a half hour; after the removal of the tube the bile diminished greatly in quantity, although I had to be padded freely for a week after getting on my feet. About a fortnight after the operation Mr. Tait cut away the first buried suture, and I removed the remainder about two weeks after. Bile ceased to come through the fistula the third week, and it was firmly closed by the sixth week. For several months I wore an abdominal bandage.

To return to the general subject. We know nothing of the true mortality of gall stones, for many cases undoubtedly die from them and are buried under diagnoses of peritonitis, obstruction of bowels, malignant disease, jaundice, colic, etc. Our knowledge of its mortality is as obscure as that of extra-uterine pregnancy was a few years ago. As to the etiology, as little is known, save it is much more common in the countries where fat forms a larger part of the dietary than in the tropics. As to diagnosis: There is usually a history of dyspepsia of varying duration before the first pronounced attack; not infrequently attacks of so-called indigestion or gastralgia, whose nature only becomes clear when jaundice happens to be associated. The shoulder pain, of which the books make so much, is very infrequent; so infrequent, in fact, as to be of no diagnostic importance. On the other hand, the pain in the vast majority of cases is epigastric, and not even referred to the liver, even when palpation shows the liver border and gall-bladder to be excessively tender. Senac ("Du Traitement des Coliques hepatique," Paris, 1870) was the first, I believe, to call attention to the fact that the pain is usually epigastric. There seems to be a belief among the profession that jaundice is almost a necessary consequence of gall-stones. Yet the fact is without a doubt that it is only when the hepatic or common ducts are completely obstructed that jaundice occurs, and even then if the stone is small it may be of so evanescent a character as to escape notice. In my own case, in all my several hundred paroxysms I never was noticeably jaundiced but twice, although my complexion was muddy. Yet I have detected bile in my urine within an hour after a paroxysm, which was followed for a couple of days by clayey stools but no jaundice.

A few days since I was consulted by a former patient, residing in an adjoining city, whose first attack came on the day after falling through a hatchway. The attack lasted ten days and was accompanied by jaundice. Now, after eighteen months, the attacks occur fortnightly, but are not accompanied by jaundice. In my own case I would explain this absence of jaundice by the stones being both very large and very small. Some so small that after the extremely painful passage of the sensitive cystic duct they found no difficulty in traversing the much more distensible and far less sensitive common duct, and occasioned only a very brief obstruction to the bile at the duodenal opening. The larger ones were so large that when shaken into the mouth of the cystic duct they would cause pain, but could not lodge or pass into the common duct, and consequently could not obstruct the flow of bile into the intestine. Early in my case I acquired the habit of daily observing my stools, and found that always after an attack, and, strange to say, sometimes a day or two before a paroxysm, the stools would be clay colored. I also observed that the gall-bladder was tender to light palpation a day or two before some attacks, although no symptoms called my attention to my liver, it being discovered by my habit of palpating this organ. Occasionally the disease is ushered in by an intermittent fever due to suppurative inflammation of the gall-ducts, and this is well to remember in doubtful cases accompanied by jaundice. We are less likely to operate for gall stones and find we are mistaken than to run up against them when we have diagnosed some other condition. Mr. Tait operated on a tumor with the diagnosis of broad ligament cyst, and found a gall bladder distended by eleven pints of fluid; the stones were removed and the gall-bladder drained below the umbilicus, with recovery of the patient.

The late Dr. Hutchinson, of Brooklyn, had, I believe, a similar experience. We may find malignant disease complicating the case, but no harm is done by an exploration. Medical treatment is, I think, of little avail in removing gall-stones when once formed. It cannot dissolve the stones, and so it must aim only to relieve the constitutional vice leading to their formation, and to assuage the torments of the paroxysms. For the constitutional vice I think exercise, temperate eating, the salines, Carlsbad water, salicylate and phosphate of soda, iron, and possibly the wild yam (*dioscorea villosa*) may be of service. But during the paroxysm, nothing, in my opinion, equals hypodermics of morphia and atropia. Hot baths and wild yam are excellent adjuvants, but for the severest pain I think nothing equals the morphia and atropine. In some attacks the wild yam gave me very prompt relief. From chloroform or choral internally I never had any benefit. Large doses of olive-oil have gained an undeserved reputation for removing large numbers of so-called gall-stones, which were, in fact, nothing but masses of saponified oil. For recurrent cases I am firmly of the belief that operation is infinitely less dangerous than delay, and the only method which promises an absolute cure.

As to operations, we may pass over such follies as the manual extrusion and consider the only two now practised, cholecystotomy and cholecystectomy.

Cholecystectomy, or excision of the gall-bladder, I regard as a thoroughly irrational operation. It was proposed and done by Langenbuch, of Berlin, on the assumption that the removal of the organ in which the stones are commonly found would cure the disease. The fact is,[1] however, that gall-stones may be formed, and are found, in every portion of the gall-ducts, from the liver-tissue to the intestine. Thornton and Tait have both removed them successfully from liver-tissue, the stones numbering, in one of Thornton's cases, as many as four hundred and forty-eight. As yet we know nothing of the office of the gall-bladder, but it would seem from Mr. Tait's investigations that it probably produces a ferment needed in digestion. To extirpate such an organ unnecessarily seems to me very bad surgery. I certainly would not assent to become a patient of an operator so illogical as to prefer the excision of the organ to simple incision. It should, in my opinion, never be an operation of election, and, if done at all, should be confined to fragile gall-bladders. Even here I think suture of the gall-bladder and omental buttress grafts may supplant it, or an artificial sac may be made from the omentum, and then the operation reduced to the conditions of cholecystotomy.

In cholecystotomy, as first planned by Petit in 1745, first performed by Marion Sims in 1878, and fought into recognition by the genius and pluck of Lawson Tait, we have the ideal operation. Ideal, I say, because it enables us to remove collections in the gall-bladder, the most common situation; at the same time it affords a channel for the bile to escape if there is any temporary obstruction, as inflammatory swelling or an overlooked stone in the common duct. If there are stones in the common duct, they can be removed by crushing, as done by Tait, or by excision and subsequent suture of the duct, as has been very successfully done by Thornton. Patients may live for years with no bile entering the intestine, so long as an exit is given to the bile by a fistula, which is a marked contrast to what the issue would be were a stone impacted in the common duct overlooked in a case of cholecystectomy. In this latter case one of two equally fatal conditions would result, either slow poisoning from the retained bile, or rapidly fatal peritonitis from the forcing by retained bile of the ligatured cystic duct. In case of a reaccumulation in the gall-bladder, very slight though the chances appear, a simple incision in the cicatrix of the adherent gall-bladder would give easy access to, and exit for, the stones. The dragging of the adherent gall-bladder at first is somewhat inconvenient and unpleasant, but in my own case it did not make itself felt more than a few months, and this summer I have rowed, sparred, swum, and played lawn-tennis without the slightest inconvenience. The danger of a permanent fistula is very slight, as it is only when an obstruction in the common duct has been unrelieved that this can occur. If from an impacted stone time may be gained for its excision or crushing, and if the obstruction is insurmountable, we can still do a cholecysto-enterostomy, as has been successfully done by Grieg Smith and Winiwarter, and thus divert the bile to the bowel and close the fistula. To suture the incised gall-bladder and drop it back exposes the patient during the first few days to the same danger as cholecystectomy, and its mortality has been enormous. As to the comparative mortality of the operations, I can give no accurate statistics of cholecystectomy, although it is far more fatal in its author's hands than cholecystotomy in Mr. Tait's. Mr. Tait has, until a few weeks ago, operated upon 67 cases, of which 3 only had died, 1 of suffocative catarrh three weeks after operation, and 2 of cancer, but none of the deaths were directly connected with, or chargeable to, the operation. Mayo Robson, Grieg Smith, Dr. Savage, and Dr. Bantock have had unbroken success with the operation as performed by Tait. Thornton a year ago had done 43 consecutive successful cholecystotomies and 8 cholecystectomies. From this it certainly appears that in the hands of men expert in abdominal surgery the mortality is extremely small. As to contra-indications, Mr. Tait wrote me, a short time since, "I know of none save malignant disease. I have removed successfully gall-stones from the liver itself, and from every portion of the biliary canals."

My conclusions are: 1. Epigastric pain, with tender liver border, gall-bladder, and clay-colored stools are the cardinal diagnostic points. Jaundice and shoulder pain are too infrequent to be of much value. 2. Medicines are of only temporary value in cases of gall-stones, as we can never tell whether we have large or small stones to deal with. 3. Early operations will cure with but a very small fatality, probably less than five per cent. 4. The excision of the gall-bladder should never be an operation of election. 5. Cholecystotomy satisfies all the requirements of the operation. 6. Recurrences are as yet unknown. 7. Medical consultations only wait for the autopsy to settle the diagnosis.

Note.—The procedure which I suggested, instead of excision of the gall-bladder, of stitching the omentum to the gall-bladder and abdominal wall, so as to form an artificial sac, has, as I learn by the *British Medical Journal* of October 25, 1890, already been successfully employed by Mr. Mayo Robson. Long ago I arrived at the conclusion that excision of the gall-bladder was never to be an operation of election, save in malignant disease, and in discussion in local societies I proposed the procedure mentioned in my paper. It is therefore with great pleasure that I have learned of so accomplished a surgeon as Mr. Mayo Robson having already demonstrated the feasibility of this procedure.

[1] The erroneous opinion that gallstones form only in the gall-bladder seems ineradicable, as a very interesting report of a case of cholecystotomy in the Annals of Surgery for November, 1890, says of cholecystectomy: "One point in its favor is that it prevents a recurrence of the conditions which necessitate the operation."

The Contagion of Small-pox.—Dr. W. F. Suiter, of La Crosse, Wis., is responsible for the following: Some years ago I attended a man suffering with a broken leg in a log-house in the lumber woods. After he had been in bed some weeks, sufficient for union to take place, he one day pulled a wooden pin out of a hole in a log beside his bunk, and wrapped around the end which had been in the hole he found a woollen rag. He amused himself by picking the rag to pieces. Just nine days later he fell sick with the small-pox, and investigation developed the fact that twenty-eight years before a family living in that house had died of that disease and the rag had been put around that pin at that time.

STUDIES IN THERAPEUTICS—ALOES.

By JOHN AULDE, M.D.,

PHILADELPHIA, PA.

ALOES is a drug which has had a somewhat varied experience, although it is but within the past few years that it has been used with proper discrimination and with benefit. The well-known pill containing aloin, strychnine, and belladonna, enjoys an exceptional popularity, due largely to the smallness of the dose and the intervals at which it is recommended; but there are certain principles which should govern its employment, which many practitioners overlook, else it might be used more frequently and with greater benefits in those cases in which this remedy is indicated. With a view to popularizing the use of the drug with the profession, I have undertaken a somewhat comprehensive study, and trust it may be the means of leading to a better understanding of the therapeutical applications of this valuable remedy, while at the same time I will point out the objections to its indiscriminate or reckless use.

Pharmacology.—The active principle is aloin, a neutral crystalline substance, but not an alkaloid; it contains also a resin, insoluble in water, a small quantity of tannic acid, and a volatile oil, the source of the odor. According to the locality from whence obtained, this active principle is spoken of as Barbaloin, Socaloin, or Nataloin, and by some these different products are regarded as isomeric. Barbaloes is reputed to be the most active, and that is the preparation generally used by veterinaries.

Poisoning from the drug occurs in both the acute and chronic form, and, as showing that the drug enters the circulation, it should be stated that albuminuria takes place in either condition—an observation which may possibly throw some light upon the cause of the rapidly increasing frequency of this malady in later years, many of the proprietary remedies now found in the market having for their active ingredient some preparation of aloes. It is to be regretted that the popular pill mentioned has become familiar to the laity, as the rage or, shall I say, mania for purgatives, seems to outstrip all considerations for health, and undoubtedly much harm has resulted from the indiscriminate use of the combination. Absorption takes place through the mucous membrane of the alimentary tract, and applied to the skin by means of friction the characteristic physiological effects are produced. Elimination is by the kidneys, the liver, and the milk, the purgative action extending to the child at the breast, showing that it is thoroughly distributed throughout the system.

The general action is that of a tonic-astringent purgative; the salivary secretion is increased, and a bitter taste occurs in the mouth; no investigations have been made with a view to determine whether or not it affects the blood-cells or protoplasm, but in all probability medicinal doses are limited in their activity to the cells lining the walls of the intestine. In small doses, acting as a tonic, the intestinal secretions are increased as well as the peristaltic movements; but taken continuously in considerable doses, aloes causes more or less engorgement of the pelvic viscera, along with an unpleasant sensation of heat in the abdomen, dryness of the throat, with irritation of the rectum, and more or less tenesmus. The efficiency of the drug is due to the presence of aloin, and from the fact observed clinically, that the action is enhanced by the presence of bile, the suggestion has been advanced that ox-gall should be combined with it as a synergist when there is a torpid condition of the liver. Upon the digestive system the action is that of a purgative, whether taken internally, applied locally or hypodermatically; and when the conditions are favorable to its activity, the size of the dose is immaterial; with an unhealthy condition of the liver, large doses cause irritation of the bowel, most pronounced upon the lower section. Increase the activity of the hepatic function by means of cholagogues (mild) or carminatives, and we have in aloes a most admirable remedy for that form of habitual constipation which is so common in all countries. The addition of carminatives not only favors the action of the drug, but contributes to prevent griping. Fortunately, when aloes is exhibited in small doses along with carminatives, it does not cause irritation that is followed by constipation, and thus the drug can be continued at less frequent intervals until there is no longer a demand for a laxative.

As a cholagogue purgative, aloes produces effects through its irritant action; the peristalsis of the duodenum and small intestine is increased, the resorption of bile is prevented, the result being that a considerable amount of material is precipitated upon the large intestine, which causes more or less irritation, and for this reason, probably, it has heretofore been assumed that the drug had a selective action upon the colon. As a purgative it acts more satisfactorily when combined with tonics, and gentian, as well as iron, have been recommended—a question which will receive due attention when the therapy of the remedy is considered. The popular dinner-pill contains aloes as the active ingredient, and it is claimed by a prominent author that he has known persons to take such combinations for years, not only with benefit, but without any bad effects.

The whole genito-urinary system is affected in the most decided manner by preparations of aloes; the bladder becomes irritated, the urine hot and scanty; hyperæmia of the uterus follows its use, and a like effect is produced upon other pelvic organs, including the rectum and kidneys. The menstrual flow is sensibly augmented, and the sexual appetite appreciably increased, although its aphrodisiac action is doubtless largely of a reflex character through its influence upon the rectum. The tubules of the kidney lose their epithelium, and the glomeruli are surrounded by an increased amount of fibrous tissue, a fact which points to the possibility of a great deal of harm being done by the injudicious use of hiera picra, which has long been with the laity a popular remedy for the relief of almost all classes of bodily ailments in women, from the age of puberty to the menopause; and there is even a superstition that it will measurably relieve the nervous manifestations which often accompany that interesting period in woman's life.

According to the experimental studies of Rohrig, Rutherford, and Vignal, aloes proved to be an active stimulant to the liver when given to fasting curarized dogs, but these observers also found that hepatic stimulation and increased intestinal secretions do not go together; they discovered that drugs which at one time greatly stimulate the liver, do not produce this effect when purgation follows their administration—an observation which will be duly appreciated by the thoughtful physician, and which may, to some extent at least, explain the theory of the so-called double action of drugs.

Therapeutics.—In considering the uses of aloes and preparations thereof as purgatives, we must bear in mind the limited range to which they are adapted. For example, they cannot be expected to act as salines and remove liquids from the system; neither can they be given in such quantity that the temperature will be perceptibly lowered, unless, perhaps, by a mere coincidence, poisonous products should accidentally be carried off; and, finally, they do not lower the blood-pressure. There are two things, however, which they do accomplish, and thus fulfil an important function, viz., they assist materially in the removal of fecal matter from the intestinal tract, and they likewise increase the output of bile. While not the only indications for aloes, the above point to the most useful and generally accepted applications, and this drug thus becomes an important weapon in the hands of the physician for the relief of habitual constipation. To avoid griping, when aloes instead of aloin is used, hyoscyamus may be permitted to take the place of carminatives, and in case there is a demand for vascular stimulants or

stomachics, nux vomica and gentian may be added with advantage; if to this we add a substantial dose of ipecac. the combination will be most efficient in the form of a pill.

℞. Aloini..... gr. ij.
Ext. nucis vomicæ,
Ext. hyoscyami..... .....āā gr. v.
Pulv. ipecac..... gr. x.
Ext. gentianæ..... gr. xx.
M., et ft. pil. no. xx. Sig.: Take one pill at bed-hour, or twice daily if required (after meals).

In case a liquid preparation is preferred by the patient, and the constipation is attended with excessive dryness of the stools, the following may be used with very good effect:

℞. Tr. belladonnæ,
Tr. physostigmatis,
Tr. nucis vomicæ,
Ext. cascara sagrada.....āā fl. ʒ ij.
Tr. aloes et myrrhæ.....q.s. ad fl. ʒ iij.
M. Sig.: Take a teaspoonful at bed-hour, gradually decreasing the dose.

The dinner-pill is highly prized by the English, owing to the slowness of action, about twelve hours being required, when a copious evacuation is produced and an overloaded colon relieved. Here the medicament is carried to the liver as digestion proceeds, the excretion of bile is augmented, and as a result, the intestinal digestion of fats and starchy products is more promptly carried forward. For this reason, perhaps, the use of aloes has been strongly recommended in the case of intestinal fermentation, with tumid abdomen and paresis of the muscular layer of the bowel. We can readily see how aloes prevents the development of these complications, and we are in a position to appreciate the empirical conclusions of earlier writers, who so strongly recommended the drug for the relief of complications in melancholic subjects.

To obtain the best effects of aloes upon the liver, however, purgative doses should be avoided, and, as a rule, it will be found that the small doses are more efficient than larger ones, while they show no tendency to set up irritation. The following formula, which depends for its activity upon the presence of aloes, I have used for the past six years for the relief of habitual constipation and that form of sick-headache which is so common among this class of people, both men and women. The original formula is one which was written for a patient, while on a visit to Wiesbaden, by a celebrated physician of that city, quite a number of years ago, and has never, so far as I am aware, been published. In order to distinguish it from other mixtures of the same character, I have usually referred to it as "The Wiesbaden Elixir," and can say candidly that it is a most efficient remedy, and is not especially objectionable to the palate. Possibly some enterprising pharmacist may deem it of sufficient value to put it in the form of a pill, when it may be found of sufficient importance to take a place side by side with Warburg's tincture:

℞. Spanish saffron..... .... gr. xx.
Socotrine aloes,
Boletus laricis,
Powdered myrrh.....āā ʒ j.
Powdered rhubarb,
Powdered angelica root
Zedoary root,
Gentian root,
Calamus root..... .....āā ʒ ij.
Brandy, q.s. to make ..... flO ij.
M. Sig.: Eight or ten drops to be taken after meals, dropped on sugar, or mixed with brandy or wine. Cold water must not be taken with, or soon after, the medicine. As a purgative, half a teaspoonful may be taken at bed-hour, or twice daily, the dose to be gradually decreased as may be deemed advisable.

Running in parallel lines with the treatment of constipation, aloes is used to control diarrhœa of a dysenteric character accompanied by tenesmus, a condition well known to all who are subject to bilious attacks. These attacks simply indicate deficiency and irregularity of the hepatic excretion, generally accompanied by, or alternated with, constipation, a complication which aloes, in the form of the elixir mentioned, is well calculated to correct. Very often the appearance of hæmorrhoids succeeds attacks of congestion of the pelvic viscera, and notably after parturition, and here also aloes has been found serviceable when given in accordance with the indications heretofore advanced. This drug, however, cannot be expected to accomplish much without due allowance being made for the various functional derangements which contribute to favor the development, and it is in this particular rôle that the elixir seems to overcome the complications.

It is said of Oppolzer, that he acquired great reputation for the successful treatment of habitual constipation, although he had but two formulæ: one when constipation coexisted, the other without constipation. In the first class of cases, quinine was added to the aloes, in the latter, iron; and the following is offered as an explanation of the phenomena: quinine in considerable doses acts as a hepatic stimulant, increasing decidedly the discharge of bile, which relieves the portal congestion, and contributes materially toward re-establishing a healthy condition of the pelvic circulation. In the absence of constipation, stimulation of the liver is not demanded, but with the addition of iron the quality of the blood is improved, and it doubtless acts in the capacity of an astringent to the mucous structures of the alimentary tract. Such persons show a greater or less tendency to subacute and chronic rheumatic troubles, and it will be advisable therefore to combine with the aloes and iron small doses of rhus toxicodendron, in the form of the tincture made from the fresh leaves.

℞. Tr. aloes et myrrhæ..... fl. ʒ j.
Tr. rhois toxicodendri..... gtt. xij.
Vini ferri amaræ..... ... q. s. ad fl. ʒ iij.
M. Sig.: Take one teaspoonful in a little water about half an hour after meals.

Where we have to deal with hæmorrhoids, and aloes preparations are indicated, it will be advisable to combine with them half-drop doses of the tincture of rhus, for the purpose of relieving the tenesmus, and assisting in meeting the demand for anodynes to overcome pain. Hæmorrhoids are often due to a costive habit and straining at stool, and will quickly disappear on judicious employment of a suitable laxative, and the adoption of a selected dietary. Small doses of aloes are beneficial when there is no active inflammatory action in progress, but large doses are always injurious.

Basing our estimate upon the foregoing premises, aloes would naturally be considered a suitable remedy for the treatment of certain forms of jaundice, but more especially those cases where hypochondriasis is a prominent factor; but discretion must be exercised in order that the medicament reaches the liver and is excreted with the bile, or, as previously suggested, it may be given in combination with ox-gall.

Providing there exists no contra-indication, aloes may be used for the expulsion of ascarides, but in all cases we must consider the decided influence which will be produced upon the uterus, as it has been known to cause abortion. In amenorrhœa aloes is a popular remedy, but it should be used only near the expected time of menstrual molimen, and then in the cases where there is an entire absence of rectal irritation. A combination can be made with myrrh, but aloes is contra-indicated in cases of suspected pregnancy. In the treatment of menorrhagia by the exhibition of aloes, iron is always indicated, tonics being often of more value than purgatives, while appropriate hygienic regulations must be insisted upon.

1910 Arch Street.

AN UNUSUAL CASE OF SHOCK FOLLOWING CONCUSSION OF THE LUMBAR SPINE.

By CALVIN L. HARRISON, M.D.,

ASSISTANT SURGEON TO THE VANDERBILT CLINIC, NEW YORK.

By permission of Dr. Charles McBurney the following abstract has been made from the history of a case of shock and spinal injury recorded during my service on Dr. McBurney's house-staff at the Roosevelt Hospital in New York. The case derives interest from probable dependence of the primary symptoms upon concussion of lumbar sympathetic ganglia through the spine.

On March 7, 1889, a boy, thirteen years of age, while at play in the streets of New York, was struck on the back by a short iron-loaded whipstock thrown at him a distance of a few feet by a boy eight years of age. The loaded end of the whipstock seemed to have struck a whirling blow upon the spine. The blow, of which the patient had subsequently a distinct remembrance, caused little or no immediate pain. Disinterested persons witnessed the occurrence. In the boy's words, his "head swam" instantly. He staggered and was caught in the arms of a bystander. Unconsciousness and collapse supervened. An apothecary, hastily called to the boy's aid, made note of his condition, and remarked especially extreme dilatation of the pupils. Dr. Robert A. Sands, surgeon in charge of an ambulance summoned from Roosevelt Hospital, found the patient, ten or fifteen minutes after injury, unconscious, with blanched skin, feeble pulse, pulse-rate eighty-five per minute, breathing shallow, quiet, normal in frequency, pupils slightly dilated and slowly responsive to light, voluntary muscles flaccid, patellar reflexes absent, no muscular movements to be elicited by pinching the skin of the extremities or by pressure upon the ulnar and supra orbital nerves; the reflexes connected with deglutition, however, still responsive, as the patient swallowed half an ounce of whiskey slowly poured into his mouth.

A few minutes later, after his admission to the hospital, I found the patient unconscious, his skin cold and pale, pupils contracted and irresponsive to variations of light, eyes rotated downward to the left, having short horizontal movements of nystagmus. Otherwise his condition was as described above. No appreciable external lesion existed. The aspect of the patient was that of one in extreme shock.

The patient having been put to bed and warmth applied to the body-surface by means of hot bottles, his pulse soon became fuller, remaining slow, his skin flushed. Twenty minutes after admission he could be partly aroused; three-quarters of an hour after admission he completely regained consciousness. Acute tenderness on pressure was then found over the spines of the third and fourth lumbar vertebræ, at which place the patient located the impact of the blow; no crepitus, deformity, ecchymosis, or swelling could be detected there. No symptoms of any head-lesion and no paralysis of voluntary muscles existed.

Not long after the patient slept naturally and soundly. When he awoke, ten hours later, he at once sat up in bed, having no pain in movements of the body. The right patellar reflex was then present, the left absent; the cremasteric reflexes were vigorous. Fæces and urine were passed normally twelve hours after the accident.

Secondary symptoms developed twenty hours after receipt of the injury. A small area of cutaneous hyperæsthesia was then found over the left anterior superior spine of the ilium, in the distribution of the ilio-hypogastric nerve. The point of injury over the third and fourth lumbar vertebræ remained very tender to pressure, in addition to which there was some tenderness on pressure over the spines of the vertebræ from the fifth lumbar to the fifth dorsal, more acute above, where it abruptly terminated. Counter-irritation over the vertebral column was applied by sinapisms, and absolute rest enjoined. On the following day the tenderness over the vertebral spines had extended to the second dorsal. Sinapisms were repeated. An area of cutaneous hyperæsthesia appeared located in the right scapular region, also a narrow area to the left of the vertebral column in the lumbar and lower dorsal regions, and two areas symmetrically disposed one on either side of the vertebral column at the level of the fifth lumbar vertebra. At the same time the area above the left anterior iliac spine had spread so as to embrace a tract of integument reaching above and below Poupart's ligament from the iliac spine to the scrotum, in the distribution conjointly of the ilio-inguinal and ilio-hypogastric nerves; this area was sharply defined. In the course of four days thereafter the dorsal hyperæsthesia extended, mainly in tracts to the right of the lumbar and dorsal vertebræ.

The patient's general condition after the first was excellent. His temperature never exceeded 99° F. He availed himself surreptitiously of all opportunities to sit up in bed, being far from complaining or imaginative, and he wished only to return to freedom and sport.

On the sixth day recession at the boundaries of the hyperæsthetic areas began. On the eighth day slight tenderness on pressure over the vertebral spines still existed from the fifth lumbar upward as high as the second dorsal, being most marked at its terminal limits. On the ninth day no tenderness remained and the patient was allowed to leave his bed. Cutaneous hyperæsthesia disappeared. On the eleventh day, no symptoms returning, he was discharged from hospital. Two weeks longer he remained under observation without symptoms.

The boy had no history of hysteria or syncope. At the time of the accident he was strong and well.

IMPERFORATE HYMEN—PREGNANCY AND OPERATION.

By CHEVES BEVILL, M.D.,

WINFIELD, ARK.

On November 12, 1887, I was called in consultation to see a girl a few months over fourteen years of age, who had been suffering great pain for four days with, what was thought by the attending physician to be, inflammation of the bladder and prolapsus uteri.

The pains came on at regular intervals, and I found upon an examination that the hymen was distended to its fullest extent, bulging the perineum like the advancing fœtal head. A soma in the bladder and the rectal touch revealed the presence of fluid. The membrane was punctured with a sharp-pointed bistoury, and the retained menstrual fluid came with a rush. Three half-pints were allowed to escape, and then I plugged the opening with carbolized lint. The lint came out three hours later, and fully as much more fluid escaped, but the patient was so weak that I thought best not to make the opening as large as it should have been.

The patient recovered, menstruated regularly, and grew to womanhood in a few months.

She married in the summer of 1889, and last June (1890) I was again consulted in regard to her condition, as she was pregnant, and the hymen was still imperforate, so far as its original condition was concerned. I advised its removal at the end of the seventh month of pregnancy.

On July 7, 1890, the thick membrane was removed. The hymen could be pushed back for two and one-half inches. The original opening was less than one-eighth of an inch in length. The membrane was pulled down with a blunt hook and removed with a Sims curved scissors. The membrane was fully one-sixteenth of an inch in thickness. After the membrane was removed, I introduced a Hale speculum and spread the vagina to a con-

siderable degree. The bleeding was but little; carbolized vaseline on cotton (absorbent) was used to keep the edges from adhering. The patient made a rapid recovery, was up in one week, went to term, and labor was completed, September 10th, without any further trouble.

I report this case from the fact that such cases are rare. I have no recollection of seeing a case reported just like the above, as they generally go on until labor has begun, and the physician has to operate at that time—which I think is attended with more danger than prior to full term. And furthermore, such cases, if they occur, are rarely ever reported from the back woods.

Cazeaux and Faner, as well as Charpentier, in their great works on obstetrics, only speak of the hymen being operated upon at the time that labor has begun.

November 10, 1890.

SOME OBSERVATIONS ON THE USE OF APOMORPHINE

By J. S HORSLEY, M.D.,

WEST POINT, GA.

CASE I.—In August, 1889, Mrs. N——, aged twenty-two, mother of four children, had a very severe attack of sick-headache. The attack began early in the morning, getting worse as the day advanced. I saw her at 3 P.M., suffering intense pain in the head, and down the spine. She said she felt as if a cord extended the whole length of the spine, and was becoming too short, so that her head was being drawn backward with each paroxysm of suffering. The pain is very severe all the time, but every few minutes a paroxysm of intense suffering comes on, which almost induces convulsions. During the paroxysm the head is drawn backward, the thumbs drawn across the palms, and the whole arm rotated inward, pupils dilated. As the stomach seemed to be somewhat distended, I gave an emetic, ten grains of powdered ipecac in a tumblerful of warm water; after half an hour, there being no nausea, and the pain appearing to be more severe, ten grains more of ipecac, with the addition of a teaspoonful of bicarbonate of soda, was given. Waiting on this fifteen minutes, there still being no nausea, and thinking that an irritant emetic might be more prompt, I gave her a teaspoonful of ground mustard in a tumblerful of warm water. After again waiting fifteen minutes with no nausea, the patient's sufferings increased to such a degree that convulsions seemed imminent, I decided to use, and gave, one-tenth grain apomorphine mur. subcutaneously. Free emesis occurred in about five minutes, with immediate subsidence of all the trouble. The patient vomited what had been eaten at dinner the day before. I have treated this patient in several similar attacks since, giving apomorphine at once, with prompt relief.

CASE II.—Mr. C— —, Irish, aged about forty-five, a hard drinker, in January, 1890, took by mistake, or with suicidal intent, about one and one half ounce of vinegar in which he had previously dissolved some strychnine. He claimed to have taken about half the contents of the bottle. One and one-half ounce remained in the bottle. I could not ascertain exactly the amount of strychnine dissolved in the vinegar; however, he used all that he procured from the druggist. The strychnine was purchased several months previous, and the druggist who furnished him lost his poison-book by fire, but thought the amount was either three or five grains.

Mr. C——'s family were not at home when he took the strychnine, and it is not known at what hour he took it, or at what time the first symptoms were manifested. I saw him at 6 P.M. A physician who happened to be passing had been called in, and had given him a hypodermic injection of morphine $\frac{1}{4}$ gr., atropine $\frac{1}{150}$ gr., about fifteen minutes before my arrival. Having treated this patient on a former occasion for an attack of suspended animation which I thought largely due to some gastric derangement, and thinking that this might be a similar case with the variations, I at once gave subcutaneously $\frac{1}{12}$ gr. apomorphine mur., which was followed in five minutes by ineffectual efforts at vomiting, and complete cessation of the spasms which had been recurring at very short intervals, the patient semi-conscious during the attack, partially asphyxiated. The patient had but one spasm after my arrival, before he was relieved by the apomorphine. Still thinking that there must be something in the stomach which caused the trouble, I decided to use the stomach-pump, which I sent for. At 7.30 P.M., with the assistance of Dr. G. H. Winston, I made several unsuccessful attempts to pass the tube, spasm of the parts preventing. The patient now began to have recurrence of spasms, the character of which led me to suspect strychnine poisoning. While recurring at short intervals, the spasms could be provoked by sudden noise, or by slapping him. Morphine and atropia were again administered subcutaneously; but after waiting a few minutes, and seeing no abatement of the symptoms, at 8 P.M. he was given $\frac{1}{10}$ gr. apomorphine. Spasms ceased at once, some nausea but no effort to vomit followed the dose. Patient's urine was now drawn with a catheter and set aside with a view to testing for strychnine. The patient was given 2 oz. castor-oil, and the dose repeated after an hour. At 11 P.M he was still resting quietly. At twelve o'clock the spasms recurred, of a character more severe than before, and death by asphyxia seemed imminent. Apomorphine gr. $\frac{1}{5}$, was given, which at once arrested the spasms, but caused no attempt at vomiting; he did not complain of nausea. At 1 A.M. he was resting well.

Very soon the patient asked for some melted hog's lard, of which he drank a teacupful. Very soon thereafter his bowels acted freely. He rested well the remainder of the night. There was no recurrence of spasms after twelve o'clock. Dr. G. H. Winston tested the urine drawn with the catheter, and found unmistakable evidence of strychnine. Two days later patient made confession of taking strychnine, and gave me the bottle containing the residue. This solution was also tested, and found to contain strychnine.

This patient has since committed suicide by the pistol route, making it probable that suicide was intended before.

CASE III.—Mrs.——, aged twenty, mother of one child about eighteen months old, has not been in good health since the birth of her child. Was called to see her in June, 1890, on account of a violent attack of palpitation of the heart, with great dyspnœa. She had had several attacks of this character before.

She was given subcutaneously one-twentieth grain apomorphine. Vomiting of undigested food followed in five minutes, together with relief of her distress.

CASE IV.—Mr. J. T——, aged twenty-three, had an aching tooth, took two drinks of mean whiskey, and repaired to the dentist, where his tooth was extracted. He returned home, five miles into the country, very much intoxicated. At 6 o'clock P.M. he put his head into a tub of cool water, and fell over with a convulsion, which his excited friends said lasted fully fifteen minutes before he breathed freely. The spasms were repeated at short intervals until I saw him at 11 P.M. He was at once given subcutaneously one-twentieth grain apomorphine. The spasms ceased, and did not return. Slight nausea but no emesis followed this dose.

Other cases could I mention illustrative of the beneficial effects of apomorphine, but I think the cases cited sufficient to present this new use of the remedy; that of preventing and controlling convulsions, and other motor disturbances. I have seen so little written on the uses of apomorphine, and that usually in relation to its action as an emetic, that I conclude that it is not appreciated at its full value by the profession. The works on materia medica and therapeutics in my collection—Brunton, Bartholow, Potter, and Trousseau, while noticing other uses of apomorphine, treat of it principally in relation to its action as an emetic.

I have not been able to find any report of the use of apomorphine in motor disturbances for other than the relief to be expected from emptying the stomach, except a case in which a German physician succeeded in cutting short epileptic attacks by the subcutaneous injection of apomorphine during the aura. See MEDICAL RECORD, November, 1884, p. 598. Dr. Edward Cockrell, of England, is reported to have successfully treated infantile convulsions by its use; see MEDICAL RECORD, May, 1884, p. 544. It is not stated whether the convulsions resulted from gastric disturbance or not; but as that is the usual cause of convulsions in children, we may suppose that its emetic action was sought in this case. I think it will be found that the remedy has hitherto been used principally for its emetic action. That certainly was my object in using it, until I accidentally found that it controlled the spasms produced by strychnine poisoning. Since that time I have been using apomorphine for all convulsions, and in no case have I yet been disappointed as to the result.

Of the action of apomorphine as an emetic, expectorant, or local anæsthetic, it is not my purpose to treat in this article; but to especially call attention to the facts here given, that it does arrest or prevent spasms and other motor disturbances. From the results obtained from its use in my limited experience, I would confidently expect it to control any spasm not caused by lesion of the brain or spinal cord. I am not yet prepared to defend any special theory to account for the relief afforded in these cases; but I think that its depressive action on the motor centres, at the same time that it excites the vomiting centre, may relieve general convulsions by substituting a partial vomiting. But whether we are able to satisfactorily explain the modus operandi or not, we have the facts to sustain the assertion that it does arrest spasm when present, and prevent it when about to occur.

It is quite probable that this remedy will be of service in controlling the spasms during an attack of tetanus or rabies. I have had no opportunity of testing its value in either case, but from the analogy existing between these affections and poisoning by strychnine, I think we might reasonably give it a trial in these affections.

I have used the remedy in quite a number of minor hysterical phenomena, and one case of convulsions of that character, with prompt relief. I have had no case of puerperal eclampsia since I began the use of this remedy, and am not able to report its effects in that dreaded affection; though its use has arrested symptoms which led me to expect an attack.

My use of apomorphine has been in doses ranging from one-eighth to one-twentieth grain, and has been uniformly by subcutaneous injection, except in one case, as an expectorant, with not better results than might be expected from other remedies of that class. I have in no case witnessed alarming symptoms from its administration. That its use is attended with danger in certain cases is too well attested to require comment.

Micro-organism in Salpingitis.—Dr. Coplin announces the discovery of a coccus very constantly present in salpingitis. The growth is in zoögloea masses, abundantly present in the lymph spaces of the tube wall. The coccus is not in the cavity of the tube, and cannot be demonstrated in the caseous contents of the tube, nor in mucopurulent material found in its lumen. It is entirely different from the coccus of gonorrhœa, and will not stain with the ordinary methods used for demonstrating the coccus of suppuration and gonorrhœa. It withstands the prolonged action of concentrated acetic acid when stained with saturated solution of methyl violet in aniline-oil water, but bleaches rapidly by any of the mineral acids in ever so weak solutions. Dr. Coplin is at present investigating these micro-organisms and expects to demonstrate their pathogenic character.—*College and Clinical Record.*

Progress of Medical Science.

The Differential Diagnosis of Anæmia.—True anæmia signifies a reduction in the quantity of blood. It occurs in an acute manner after hemorrhages, or it may be chronic as a manifestation of emaciation of the organism. Quantitative anæmia is characterized by pallor, although the latter symptom may be present even when the blood is qualitatively and quantitatively normal. This latter condition is present in syncope, where the patient has not lost a drop of blood, but bleeds, says Dr. Neusser, "in his own abdomen," the cutaneous vessels being contracted and the intestinal dilated. In collapse an anæmia similar to that of syncope is present. The former are considered by Neusser as prototypes of acute pseudo-anæmia, and are to be differentiated from chronic pseudo anæmia, which originates in an irregular distribution of blood, as in exophthalmic goitre and the so-called nervous anæmia attended by violent pulsations of the aorta. A form of true anæmia attended with qualitative changes of the blood is chlorosis. Chlorosis is characterized by a diminution of the coloring matter of the blood, the red corpuscles not being diminished in number. The pronounced anæmia of the mucous membranes and the skin and the fugacious œdema are not pathognomonic of chlorosis, being also present in post-hemorrhagic anæmia. Dyspeptic chlorosis is referred to as anæmia accompanied by gastric disturbances, the latter being symptomatically most prominent. Gastric disturbances are nearly always present in chlorosis, and are characterized either by chemical or mechanical functional disturbances of the stomach. The chemical disturbances result in either increased or diminished acidity of the gastric secretion, the latter prevailing. In some cases hydrochloric acid may be entirely absent. This latter condition is also present in atrophy of the gastric glands, pernicious anæmia, and carcinoma of the stomach, thus making the differential diagnosis often difficult. In carcinoma of the stomach, the contents nearly always show an acid reaction due to the presence of lactic acid, notwithstanding the absence of hydrochloric acid, and the quantity of pepsin is diminished. In the dyspeptic forms of chlorosis, on the contrary, notwithstanding the absence of hydrochloric acid, pepsin and peptones are always present. Regarding treatment, Neusser says that many cases are cured by simple iron treatment, whereas in others, not only is the iron badly tolerated, but it intensifies the gastric disturbances. The intolerance of many forms of dyspeptic chlorosis for iron may be removed by previous inhalations of oxygen, of which large quantities must be used. He begins with 50 quarts daily, and quickly increases this to from 100 to 200 quarts. Crude and desiccated blood have been employed in the treatment, and although he has used them, they were discontinued in consequence of diarrhœa being developed. From many sources it has been observed that in patients with chlorosis, who could not tolerate any preparation of iron, the ingestion of large quantities of raw meat was attended with successful results. This latter method seems in no wise irrational, as when raw meat is consumed the iron is introduced in the form of hæmoglobin, which is at once taken up by the circulation. The objections to it are the obnoxiousness of raw meat to many patients, and the danger of tænia. Aside from the objections already cited, the meat diet is often contraindicated in those cases attended by *fetor ex ore*. The odor is largely derived from scatal, a ptomaine derived from animal food, and for this reason an absolutely vegetable diet is indicated. —*Occidental Medical Times.*

Dr. O. W. Holmes says it is not true. The poet-physician has had it brought to his notice that a learned small girl of Boston has spoken of him as having been for many years a "Professor of Monotony at Harvard University."—*Maryland Medical Journal.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 6, 1890.

THE CURABILITY OF GALLOPING CONSUMPTION.

THE announcement by so well-known a physician as Dr. McCall Anderson that acute phthisis, or galloping consumption, is curable, excites a good deal of surprise and quite as much incredulity, yet Dr. Anderson reports in the *British Medical Journal* seven cases of this character, of which five recovered.

Acute phthisis is considered by Dr. Anderson to have two forms, acute tuberculosis and acute pneumonic phthisis. Some of his cured cases were of the tubercular character. The treatment advised is given in detail and contains no especially new feature.

"The principal indications," he says, "are: 1, to keep up the strength; 2, to keep down the fever; and 3, to treat any special symptom or complication which may arise.

"1. Two thoroughly-trained and reliable nurses are indispensable, one for day and the other for night duty; for without admirable nursing no hope of improvement can be entertained; and the hygienic and other surroundings of the patient should be satisfactory, so that we need not be surprised that, when the disease occurs in the homes of the working classes it is almost necessarily fatal, and that hospital patients have the best chance of recovery. The patient must be fed constantly on fluid food (soup being avoided if diarrhœa is present) both day and night, and stimulants (from ℥ ij. to ℥ x.) are required early in the attack, but should be given in small quantities, frequently repeated and along with the food. In fact, the dietetic treatment should correspond with that of a case of fever presenting symptoms of a similar degree of severity.

"2. At bedtime a subcutaneous injection of sulphate of atropine (gr. $\frac{1}{100}$ to gr. $\frac{1}{60}$) is given. This checks perspiration when present, acts as a sedative to the system, indirectly helps to reduce the fever, and diminishes the secretion from the lungs.

"3. Remedies are given with the view of lowering the temperature. This is a point of the utmost consequence, because the majority of the patients die consumed by the fever. Some benefit is derived by allowing the sufferer to suck ice freely, by giving the food and drinks iced, by sponging the body with iced vinegar and water, or even by using iced enemata. But our main reliance is upon one or more of the following methods:

"(*a*) Niemeyer's antipyretic pill or powder every four hours, containing gr. j. quinine, gr. ½ to gr. j. digitalis, and gr. ¼ to gr. ½ opium. The proportion of opium may even have to be increased beyond this if there is much diarrhœa. The effect of the digitalis must be carefully watched, and it must be omitted for a time if the pulse becomes preternaturally slow and irregular and the secretion of urine very scanty.

"(*b*) The administration daily—particularly shortly before the temperature tends to be highest—of from ten to thirty grains of quinine, given, as suggested by Liebermeister, either in a single dose or, at all events, within an hour.

"(*c*) The application of iced cloths to the abdomen for half an hour every two hours so long as the temperature exceeds 100°. The application of iced cloths is made in this way:

"The night-dress is pulled well up over the chest so as to avoid any possibility of its being wet, and, for a similar reason, a folded blanket is placed across the bed under the patient's body. The usual bedclothes are arranged so that they reach up to the lower part of the chest only, which latter is covered by a separate blanket in order to prevent unnecessary exposure while the cloths are being changed. Two pieces of flannel are employed, each being sufficiently large when folded into four layers to cover the whole of the front and sides of the abdomen. One of these, wrung out of iced water and covered with a piece of dry flannel to protect the bedclothes, is applied, while the other is lying in a tub of iced water at the side of the bed. The pieces of flannel are changed every minute, or so often that they still feel cold when they are removed. The changing of the flannel, particularly when two persons are in attendance, one to remove the bedclothes and the flannel, the other to apply the piece which is freshly iced, can be accomplished in a few seconds."

THE MORBID ANATOMY OF DIABETES MELLITUS.

IT is only within a comparatively recent period that much study has been devoted to the pathological findings in diabetes, and our knowledge on the subject may be said to be, even yet, very rudimentary. The teachings of different authorities are by no means in accord, and it is difficult for the inquiring student to find any satisfactory presentation of the subject. An excellent summary of our present knowledge concerning the morbid anatomy of this disease was given by Dr. Robert Saundby in the "Bradshaw Lecture" delivered in London in the latter part of last August.

The lecturer began his review with the lesions of the nervous system. He believed that the brain was seldom normal. This belief, although at variance with the mass of accumulated testimony, was, nevertheless, in harmony with the more recent observations. Many of the changes found in this organ are not peculiar to diabetes and must be regarded as purely accidental, yet in a few cases localized lesions of more or less importance have been noted. Among the most significant of these are tumors in the fourth ventricle and medulla. In many of these cases there could be no doubt, in the speaker's opinion, of the direct dependence of diabetes upon the new growth. There is

apparently a tendency in the diabetic brain to the formation of cysts in the white substance, but hemorrhage does not seem to be a constant, or even a common, lesion. In a certain number of cases diabetes has very evidently resulted from the extension of diseased processes from the spinal cord into the medulla, as in locomotor ataxia and insular sclerosis. Not infrequently, also, this disease has followed injuries to the cord, and Schiff has shown that glycosuria may be produced artificially by section of the cord opposite the second dorsal vertebra. In some cases in which the cord seemed to be normal a careful examination had usually revealed the presence of nutritive changes similar to those found in many instances in the brain. Three cases have been observed in which diabetes mellitus was associated with tumors compressing the vagus nerve. These cases are interesting in connection with recent experiments showing that the disease may follow an artificially induced neuritis of the central end of the divided vagus, a similar lesion of the peripheral end causing polyuria, wasting, boulimia, and excessive thirst. Glycosuria has also been induced by an artificial neuritis of the roots of the first pair of spinal nerves. On the other hand, clinical observation has revealed the existence of a secondary diabetic neuritis. Enlargement and thickening of the sympathetic nerves and ganglia have been observed, and Dr. Saundby had himself found the semilunar ganglia enlarged in three cases, and in one there was atrophy of the nerve-cells associated with increase in the amount of connective tissue. Hale White has recently described four cases in which similar lesions were found, though, on the other hand, Shingleton Smith has made numerous examinations of the sympathetic ganglia in glycosuria without being able to find any definite or uniform lesion. The lecturer had also had three cases in which no changes could be discovered in the semilunar ganglia, although he had never found these ganglia altered when diabetes was not present.

There seems to be no constant or characteristic lesion of the heart in diabetes. Pericarditis is occasionally found, but valvular lesions are quite exceptional. The blood commonly presents a normal appearance to the naked eye, though occasionally it is dark, and in some cases very obviously loaded with fat. The red corpuscles are very often reduced in number and there is then a corresponding reduction in the amount of hæmoglobin. The alkalinity of the blood serum is reduced. As to the presence of acetone there are many conflicting statements, and the lecturer said that his own experiments, conducted some years ago with a view to determine this point, had given negative results.

Pathological alterations in the lungs may be said to be the rule in diabetes, and in perhaps no other organ are changes more constantly found. The most common condition is congestion, or congestion with œdema, the next most frequent complication being phthisis, while pleurisy and empyema are of comparatively rare occurrence. The vessels of the lungs have been described as undergoing hyaline and fibroid thickening, but this is not a primary change, nor can it be considered as in any way peculiar to diabetes.

Dr. Saundby was inclined to regard as erroneous the opinion, at one time pretty generally held, that the liver is healthy in those suffering from diabetes mellitus. He had usually found the organ enlarged, though occasionally smaller than normal. Fatty degeneration was, in his experience, very common, and the organ was sometimes markedly congested. Frequently there was a certain amount of interstitial hepatitis which occasionally went on to distinct cirrhosis. This form of cirrhosis was commonly associated with bronzing of the skin, though there might be no deposit of pigment either in the integument or in the liver itself. Notwithstanding its usual fatty appearance, Weil and Abt had not found that the diabetic liver contained an undue amount of fat.

The spleen has frequently been described as normal; the most common naked-eye change, when any is present, being that the organ is pale, small, and soft. Glycogen has been found in it.

Since Lancereaux drew attention to the frequency with which the pancreas is atrophied, going so far even as to associate the clinical type of *diabète maigre* with this lesion, much interest has been taken in the study of the changes in that organ. And this interest has been even greater since the investigations of Minkowski, Lépine, and others have shown that glycosuria followed the extirpation of the pancreas in animals. The results of these experiments have received some clinical confirmation in the case of Dr. William T. Bull's patient, who died from diabetes after extirpation of the pancreas. As far as Dr. Saundby's own experience went, he was disposed to agree with Lancereaux, as he had found a shrunken pancreas in all his own cases of typical wasting diabetes. Duffey has reported a case of diabetes associated with pancreatic carcinoma. On the other hand, Handfield Jones, and, more recently, Norman Moore, have collected reports of many cases of pancreatic disease in which no mention was made of diabetes. It has been suggested that atrophy of the pancreas may be secondary to disease of the cœliac plexus, yet Lustig has extirpated this plexus without producing any atrophy of the organ.

Various morbid changes have been noted in the stomach, and in only one case out of eleven had the lecturer found this viscus normal. Congestion or catarrhal conditions of the intestinal mucous membrane are not at all uncommon.

In every one of Dr. Saundby's cases lesions of one sort or another were found in the kidneys, though in many the changes were apparently of no great significance. The most common condition appeared to be a slight degree of fatty degeneration. Such kidneys were most commonly enlarged, their capsules being often adherent; less frequently they were congested. The most interesting microscopic lesion found in the diabetic kidney is hyaline degeneration of the tubular epithelium, first described by Armauni, and confirmed later by Ebstein. The latter located the seat of the lesion in the descending limb of Henle's tubes, and regarded the change as characteristic of, and peculiar to, diabetes mellitus. In some cases, chronic diffuse nephritis is present.

The bladder is usually normal, yet not very infrequently is dilated and hypertrophied, the mucous lining being occasionally the seat of hemorrhages.

This brief review of the various lesions associated with diabetes mellitus would seem to show that the disease, so far from having no morbid anatomy, has one of a very complicated kind, and one, the lecturer thought, that

must necessarily have some bearing on its pathology. The wasting of the pancreas is perhaps the most important lesion, but a more careful study of the lesions of this organ in a larger series of cases is necessary before we shall be in a position to estimate their real value. The changes in the abdominal sympathetic may also be found to possess great importance, but they are too inconstant to form as yet the basis of any satisfactory theory. The liver changes, Dr. Saundby thought, are probably altogether secondary to functional hyperæmia, and the other lesions, in the heart, lungs, kidneys, and brain are, in all probability, merely the results of defective nutrition, and of long-standing hyperglycæmia.

VIVISECTION AND EXPERIMENTAL SURGERY.

It is to be hoped that public opinion will not be unduly disturbed upon the subject of vivisection until the exact merits of the case of the boy and the dog have been decided. This case, through the enterprise of the daily press, and without, we are assured and believe, the connivance of the surgeon, has been widely advertised during the past two weeks. Dr. Phelps, having a patient with an ununited fracture of the tibia, which had failed to heal under the ordinary methods, undertook to transplant the bones from the foreleg of a dog into the leg of the patient. The dog necessarily had to be bound up in plaster of Paris, and to be kept in an uncomfortable position for a long time. The animal was given morphine, however, *pro re nata*, and apparently suffered very little. The main question is whether the operation was wisely conceived and necessary, and was finally satisfactory in its results. From the well-known character and reputation of Dr. Phelps we feel assured that his work in this case was scientific as well as original, and we are informed that it was entirely successful. The restoration to usefulness of a cripple and the establishment of a physiological fact of practical surgical importance is certainly worth two weeks of discomfort and even maiming of a city cur, whose ultimate end would be slow starvation, and the pound.

News of the Week.

Suit Against a Hospital.—In a suit for $15,000 damages recently brought against the Manhattan Eye and Ear Hospital, Judge Lawrence rendered the following decision in favor of the defendant: "It is well settled that a corporation established for the maintenance of a public charitable hospital, which has exercised due care in the selection of its agents, is not liable for injury to a patient caused by their negligence (McDonald *v.* The Massachusetts General Hospital, 120 Mass., p. 432; Fir-Ins. Patrol *v.* Boyd, 120 Penn., p. 624; Proctor *v.* Manhattan Eye and Ear Hospital, reported in MEDICAL RECORD, vol. xv., No. 25). In the complaint in this action there is no allegation that the defendant failed to exercise due care in the selection of its house surgeon, nor that he was not perfectly competent and skilful in his profession. It follows, therefore, that there should be judgment for the defendant upon the demurrer, with leave to the plaintiff to amend, on payment of costs."

The Intelligent Foreigner on British Piety.—According to the *Zeitschrift des Oesterr. Apoth. Vereins*, a special prayer-book for medical men has just been published in England. It contains a selection of suitable prayers for delivery on the occasion of surgical and other operations. There should be a companion prayer-book for the patient.

Dr. Otis and American Art.—The following note from the daily *Times* will doubtless interest our readers: "The departure of Dr. Fessenden N. Otis, of this city, for Europe, in search of health, is quickly followed by the sale of his collection of modern paintings and Japanese bronzes already announced. They will be sold at the Fifth Avenue Art Galleries on the evenings of Thursday and Friday, December 4th and 5th. While the collection of Dr. Otis is neither so large nor so valuable as many others in the city, special circumstances make this sale one of the most notable of those during the last ten years. For Dr. Otis bought American pictures, and his collection brings to light names which have long ceased to be seen on the catalogues of the Academy, or heard from the lips of an auctioneer."

Bogus Medical Colleges in Vermont.—Vermont is earning an unenviable reputation for its bogus medical college industries. An attempt has been made to put a stop to it, but the bill drawn up for this purpose recently failed to pass. The *Vermont Standard* says very pertinently, "there is no point on which gentlemen are so sensitive as in the matter of taking any steps which may look like abridging their liberties in the way of being humbugged."

Free Public Baths.—The Association for Improving the Condition of the Poor has undertaken the erection of free public baths. The building for the purpose will have a large reading room, with an open fireplace, and twenty-four large apartments for the bathers. There are to be no plunge baths or tubs, the society believing that for the better preservation of the health of the patrons shower or spray baths should be provided. Each apartment is to have a subdivision, to be used as a dressing room. The baths will be open to women on three days a week and to men on three days. Tickets, calling for a towel and a cake of soap, will be sold at five cents each, and they will be distributed or sold in various parts of the city. Hot coffee will be given to those who desire it on leaving the bath in the winter months. It is estimated that one thousand persons can bathe each day. Much credit is due to Dr. S. Baruch, of this city, for his earnest agitation of this subject.

The Mattison Prize—Opium Addiction as Related to Renal Disease—A Prize of Four Hundred Dollars.—With the object of advancing scientific study and settling a now mooted question, Dr. J. B. Mattison, of Brooklyn, offers a prize of $400 for the best paper on "Opium Addiction as Related to Renal Disease," based upon these queries: Will the habitual use of opium, in any form, produce organic renal disease? If so, what lesion is most likely? What is the rationale? The contest is to be open for two years from December 1, 1890, to either sex, and any school or language. The prize paper is to belong to the American Association for the Cure of Inebriety, and be published in a New York medical journal,

Brooklyn Medical Journal and *Journal of Inebriety*. Other papers presented are to be published in some leading medical journal, as their authors may select. All papers are to be in possession of the Chairman of Award Committee, on or before January 1, 1893. The Committee of Award will consist of Dr. Alfred L. Loomis, President New York Academy of Medicine, Chairman; Drs. H. F. Formad, Philadelphia; Ezra H. Wilson, Brooklyn; Geo. F. Shrady, and Jos. H. Raymond, editor *Brooklyn Medical Journal*.

For the Treatment of Enuresis in children, Dr. Kupke recommends very highly fluid extract of rhus aromatica (sweet sumach), in doses of five to fifteen drops.

Surgeon-General Baxter.—We learn with profound regret that Surgeon-General J. H. Baxter was stricken with paralysis on December 1st, and at the present time of writing is hardly expected to live.

Macon County (Ga.) Medical Society.—On the evening of the 18th inst., the following were elected officers of the Macon (Ga.) Medical Society: *President*—Dr. R. O. Cotter; *Vice-President*—Dr. H. J. Williams; *Secretary and Treasurer*—Dr. H. P. Derry; *Corresponding Secretary*—Dr. H. McHatton.

Removal of the Gasserian Ganglion for Neuralgia.—Mr. William Rose, Surgeon to King's College Hospital, recently reported to the Medical Society of London the successful removal of the Gasserian ganglion for persistent neuralgia.

Washington Obstetrical and Gynecological Society.—At the annual meeting of the Washington Obstetrical and Gynecological Society, the following officers were elected for the ensuing term: *President*—W. W. Johnston, M.D.; *Vice-President*—D. W. Prentiss, M.D., and H. L. E. Johnson, M.D.; *Recording Secretary*—H. B. Deale, M.D.; *Treasurer*—George Byrd Harrison, M.D.; *Corresponding Secretary*—G. Wythe Cook, M.D.

New Hospital in Norwich, Conn.—Norwich is to have a new hospital. Two citizens have given $100,000 and $50,000 respectively, and the property has been purchased.

Deaths from Phthisis.—In the last ten years there have been 52,160 deaths from phthisis in this city, or 14.12 per cent. of the total deaths.

Dr. John T. Howe, after an illness of two months, died on December 1st in his apartments in this city, Twenty-fourth Street. He was born in Chatham, N. B., twenty-nine years ago, and was graduated from the University Medical College of this city in 1888.

Cancer Mortality Among the Jews.—An English paper states that one of the lecturers at Owens College, Manchester, not long since put forward the assertions (1) "that no Jew or Jewess has ever been known to suffer from cancer;" and (2) that "the immunity of the Hebrew race from this frightful scourge was attributed to their abstinence from swine's flesh."

All Pleurisies, even the simpler forms, are of bacterial origin. Such was the opinion generally expressed at a recent meeting of the Italian Medical Congress.

KOCH'S METHOD AND WHAT MAY BE EXPECTED OF IT.

By Direct Cable to the Medical Record.

(From a Staff Correspondent at Berlin.)

Berlin, December 4, 1890.

It is hardly necessary to write in detail about the particulars pertaining to Koch's method for the treatment of tuberculosis, as they have already found extensive publication. The inoculations are made in all the public institutions at the present time and the facilities for the reception of tubercular patients are constantly being increased. Of the European physicians who were attracted here by Koch's paper of November 13th, most of them have returned, and American physicians are now arriving. Of those now here from the United States, I may mention Drs. Ernest, of Boston; Abbott, of Baltimore; H. P. Loomis, Lindsley, Einhorn, and Stearns, of New York, and Dr. Von Ruck, of Asheville, N. C. American patients are also arriving, but find it difficult to receive the care and treatment they seek, and some of them are returning home, preferring to wait until they can receive the treatment there.

I have since my arrival visited many of the clinics, and desire to call particular attention to the exhibition of patients by Dr. Gerhardt, at the Charité, and his remarks made to physicians in connection therewith. Dr. Gerhardt spoke in particular of Koch's lymph as a specific in its action upon tubercular tissue, and mentioned its importance as a diagnostic means, equal to the demonstration of the tubercle bacillus, but, like it, not infallible. As to the therapeutic results, he said the time is altogether too short to form any opinion, and a year or two must elapse before we can correctly appreciate its value in his cases. He called attention to the occasional occurrence of hæmoptysis after the injections as probably referable to the so-called stage of reaction, and counselled great circumspection, especially in considerably advanced cases. The reaction, he said, was by no means uniform. In some cases the fever might appear in a few hours, in others it occurred later, even as late as twenty-four hours, and in three cases which he showed it did not occur at all, although one patient had received five centigrammes.

Dr. Ewald has treated 90 cases at the Augusta Hospital since the first introduction of the method, and of the results thus far he says in most of them their condition has been ameliorated. There is a state of euphoria, a better state of subjective feelings, improved appetite, disappearance of night-sweats, less cough, etc., but physical examinations of the chest show no changes, unless an increase of the moist sounds during the stage of reaction and subsequently. New features are constantly being observed and the cases differ greatly, not only in the degree and duration of the fever but also in their state-

ments as to headache, general malaise, nausea, and various other sensations. He also observed various exanthems, and one case typical with that of scarlatina.

A post-mortem examination of a case with extensive lung disease and intestinal tuberculosis, and far advanced in the disease, and who had received one injection shortly before he died, revealed nothing characteristic upon the tuberculous ulcerations in the intestine as due to the inoculation. In speaking of the method he pointed out the difference between the preventive inoculations of Jenner and Pasteur and the repressive effect upon an established tuberculosis by Koch's method.

At the City Hospital, which has been designated as the central station for Koch's method, the Director, Dr. Guttmann, has set apart ninety beds for cases to be treated by inoculations, and Dr. Koch comes there personally to witness the results. Very exact graphical records are kept, showing the various symptoms of the stage of reaction and also of the number of tubercle bacilli in the expectoration, which is examined daily by Professor Ehrlich, who has taken charge of the bacteriological laboratory. There Director Guttmann demonstrates a great many cases daily and his observations coincide with those of Professors Gerhardt and Ewald in every particular.

From all this it may be seen that the state of affairs concerning this work and its clinical features is simply that of gradual accumulation of experience and knowledge, and the opinion is here very general that visiting physicians will be able to learn and see much more three or four months hence than at the present time. Patients certainly should be discouraged from coming here, especially since in a very short time the treatment will be carried out in American institutions, but, above all, because nothing is as yet certain or settled as to the results.

In the *Deutsche Medicinische Wochenschrift* of December 4th the following new investigations on the influence of Koch's medium on tuberculosis are published:

"Observations on the reactions which appear after the use of Koch's medium," by O. Rosenbach, of Breslau. Rosenbach advises the following classifications: (*a*) Suspicious cases, *e.g.*, catarrh of the apices, without bacilli in the sputum, and phthisical cases, *e.g.*, vomici and old excavations and with bacilli. (*b*) With absence of bacilli but clinically of a phthisical nature. (*c*) Phthisical infiltrations with bacilli appearing during a long period of observation but with either no fever or very slight fever. (*d*) Joint affections of a dubious character. (*e*) Clinically undoubtedly tubercular. (*f*) Affections of the bowels. (*g*) Affections of the larynx.

Having examined all these species, although necessarily but for a short period, Rosenbach arrives at the following conclusions: 1. It is always advisable to begin with small doses, namely, one milligramme, and, if there be no reaction fever, to increase the dose by degrees. After the patients have become used to small doses they can be increased gradually, with longer intervals between each dose, and always with the greatest caution. 2. In phthisis of the larynx there was reaction in only one case. 3. The time at which the injection is administered has an influence on the febrile reaction, the temperature rises quicker and higher if the injection be made at the time when the fever usually comes on. 4. The injection is made by Pravaz's hypodermic syringe containing one cubic centimetre of Koch's fluid, which must be diluted with one-half per cent. solution of carbolic acid before the injection is made. The best place for making the injection is the cutis of the abdomen.

C. von Noorden, of Berlin, Gerhardt's Klinik, has also written a paper on "Early Changes in the Lung under the Influence of Koch's Method of Treatment." A female patient, with lupus of the nose, was treated by Koch's method. The lungs and other organs were apparently in a normal condition. On November 21st the first injection was made of five milligrammes of Koch's fluid. In the evening the temperature rose to 38.8° C., the respirations were 42 and the pulse 110, the lupus spot on the nose became reddened and swollen, the commencement of ulceration became evident in the larynx, and the patient complained of pains in the right side of the chest. November 22d: The fever continued; temperature, 39° C.; pulse, 122; respiration, 58; over the lung there was exceedingly loud breathing. Expectoration, which had not existed before, now came on profusely and was of a muco-purulent character; there were no bacilli. November 23d: apices, anteriorly dulness and fine râles; respiration, 30; temperature normal. November 24th: Cough less, no expectoration; the dulness and râles were lessened. November 25th: At 10 A.M. one centigramme was injected. At 3 P.M. there was chill, cough, and expectoration; temperature, 40° C.; pulse, 132; respiration, 60; again dulness and râles. November 26th: The patient was restless during the night; the temperature fell slowly to 38.8° C.; respiration 68. In the morning, on the affected portion of the lung, bronchial breathing was found, with crepitant râles. The spot of lupus on the nose became again swollen, but not so much as after the first injection. November 27th: The temperature fell to 36.5° C. and the respiration to 30.

There was sweating and much dry cough. The condition of the lung remained as before, and there were no bacilli in the sputum. November 28th and 29th: Showed a gradual decrease in the dulness. November 30th: The dulness had nearly disappeared, and the breathing had become normal.

The author describes four more similar cases in which tuberculous spots could not be recognized by physical signs before the injection. After the injection they could

be diagnosed by physical signs in the lungs; the affected part of the lung, after injection, became more infiltrated and thickened.

The time for the appearance of these changes varies twenty-four hours. After their appearance they usually begin to decrease. The author also warns against using Koch's remedy in cases where large portions of the lungs are affected; for by the thickening of the lung after the injection there is a diminution of space for the air in the lung which might become fatal in these advanced cases. These transitory infiltrations probably bring on the healing process.

Dr. E. Kromeyer, of Halle, examined portions of lupus tissue excised from a patient affected with that disease, and concludes that the injection brings on an inflammation of the structures surrounding the tubercle, which results in suppuration of the same.

More Facts Concerning the Koch Treatment.—Our correspondent from Berlin writes, under date of November 20th: "The excitement here over the new treatment of tuberculosis is so great, the expectations for its success in everything of a tuberculous nature is so unlimited, that it is at present difficult—one might better say it is impossible—to come to any intelligent conclusion as to its value or its limits. Furthermore, it has been under trial for too short a time, as the treatment was begun here less than two months ago, in Dr. Levy's private hospital. Conservative men, however—many of them—think that the reaction will come sooner or later, as the popular expectations concerning it are altogether too extravagant. Still, results may be seen here daily which are simply amazing to the most incredulous.

At present, cases of the following nature are under treatment at Dr. Levy's hospital, and have been seen by the writer: Lupus, tubercular (?); diseases of temporal bone (following chronic purulent otitis); tubercular (?) glands of the neck; tubercular (?) disease of the tarsal bones, of larynx, of coccyx; pulmonary phthisis; tubercular (?) tumor of iris, etc. The course some of the cases have pursued is exceedingly striking. For example, tubercular disease of tarsus. The child, three or four years of age, showed a characteristic fistulous opening over the tarsus of left foot, discharging scanty thin pus. This case had been of several months' duration. After the first injection, which was followed by the usual severe constitutional symptoms, the foot became swollen, red, tender, and painful, and the discharge became thick and creamy; as the constitutional symptoms abated in severity, so also did the local symptoms. After two or three days the injection was repeated, and was again followed by the general and local symptoms. After the fourth injection (given almost always in the back) the sinus closed. The next two injections were not attended by constitutional symptoms, but only by some redness around the site of the former sinus. The next injection was followed neither by general nor by local symptoms, and in consequence was pronounced cured. To-day the foot is not swollen, not painful or tender, the sinus is closed and covered by a firm pink scar.

Another case, a woman, about twenty-five years of age, with the characteristic scars in neck, dating from childhood, was admitted with very large (one nearly the size of a hen's egg) tuberculous (?) glands under the chin and at the angle of the jaw. The first injection was followed by most violent constitutional symptoms (temperature 106° F.), so that the injection was not repeated for several days. At the same time the general symptoms developed, the glands increased in size, and became red and tender. After a few days the injection was repeated, and she has now had three or four. The glands have diminished fully one-half in size. Case still under treatment.

"The child with tubercular disease of temporal bones, in addition to the general symptoms, always complains of pain in the ears, puts his hands up to the ears, crying, etc., after an injection.

"The case of so-called tubercular tumor of the iris has had no reaction following the injection, and the diagnosis will accordingly be modified.

"The cases of lupus have been often described, and the change in the appearance of the patches is oftentimes astonishing. Many turn black, and look as if they had been burned with the actual cautery.

"The material used is a brown fluid, which is used in ten per cent. watery solution, and of this the dose varies from 0.1 to 0.01 c.c. The largest dose used at Dr. Levy's has been 0.7, and the patient was comatose for the following forty-eight hours, and it was hardly expected that she would recover. Not a few cases have become unconscious after the injection. Little is publicly known as to its composition. Even Koch's assistant assured the writer that he did not know it. I have been told that it contains no germs, but that it is a product, the result of the changes produced in the nutrient material by the germs, like the ptomaïnes (Stoffwechsel producte). It is absolutely impossible to procure any of the material at present, and probably will be for weeks to come. The maker, Dr. Libbertz, has been so besieged for the material that he has disappeared from view. No one can find him.

"The remarkable fact is, that the material does not kill the bacilli, as Koch himself expected it would do. The tubercle-containing tissue is separated from the healthy tissue, and yet in the former are the living bacilli."

Professor Koch's Lymph.—The material used by Professor Koch in his inoculations for tuberculosis is a viscid fluid, the color of a dilute solution of iodine, is of a slightly syrupy consistence, and is supplied in white glass corked bottles containing each about forty grammes. It is prepared for use by adding one hundred grammes of sterilized water, the maximum dose of injection being one gramme. The injection is made subcutaneously in any part of the body, but preferably between the scapulæ. No reaction appears locally, but at the end of four hours severe constitutional effects are manifest in the appearance of rigors with malaise, followed by a temperature which may reach 106° F., with a corresponding increase in the pulse-beat from 120 to 160. Vomiting frequently occurs at the acme of the fever. In some cases the reaction is attended with alarming symptoms, very great prostration, requiring the use of stimulants, and severe dyspnœa. When the tuberculous deposit is super-

ficial there is in and around it great tumefaction. The amount of constitutional disturbance is said to be governed by the extent of the tubercular deposit. This is noted particularly in cases of lupus and in tuberculous glands of the neck. The constitutional symptoms are usually of short duration. Subsequent injections are not attended with systemic disturbances. Over the surface and in the neighborhood of tuberculous swellings, scabs appear which, on being separated, leave healthy granulating surfaces. Cases in that stage are said to be cured, in as much as they show no constitutional reaction.

THE PROTECTION FROM DIPHTHERIA AND TETANUS BY INOCULATION.

(By Direct Cable from Berlin.)

BERLIN, December 4th.

By the courtesy of the *Deutsche Medicinische Wochenschrift* your correspondent has received advanced proofs of an article on the prevention of diphtheria and tetanus in animals, based upon experiments in the Hygienic Institute, at Berlin, made by Dr. Behring, assistant in the institute, and Dr. Katasato, of Tokio. After long experimentation these observers claim to have cured animals suffering from either of these diseases—diphtheria and tetanus—by the inoculation of the serum from the blood of animals already infected. It is claimed by a large number of experiments, first, that the blood of rabbits protected from tetanus possesses the property of destroying the tetanus poison. Second, that this property is possessed by the non-cellular serum obtained from the blood. Third, that this property is of so constant a nature that it also remains active in the organism of other animals, so that notable therapeutic effects are produced by the transfusion of blood or serum. Fourth, the property of destroying the tetanus virus is absent in the blood of those animals which are not protected against tetanus, and if the tetanus virus is injected into non-protected animals, it can be so demonstrated, even after the death of the animals, in the blood and in the other fluids of the body.

In the test of the degree of immunity a rabbit previously protected received 10 c.c. of a germ containing virulent tetanus bacilli culture, of which $\frac{5}{10}$ c.c. sufficed to make a normal rabbit yield inevitably to tetanus. The protected rabbit remained entirely healthy. He had not alone secured immunity against infection with living tetanus bacilli, but also against the tetanus virus, as he tolerated twenty times the amount of a poison which suffices to kill, without exception, normal rabbits.

Blood was taken from the carotid artery of this rabbit. From this fluid blood (before coagulation) $\frac{2}{10}$ c.c. were injected in the abdominal cavity of one mouse; $\frac{5}{10}$ in that of another mouse. At the end of twenty-four hours both animals, together with two mice were injected with virulent tetanus bacilli, and to such an extent that they were attacked by tetanus twenty hours afterward, and died in thirty-six hours. On the other hand, both previously treated mice remained permanently healthy. The larger amount of blood was allowed to stand until serum had formed abundantly, and of this serum six mice received each an injection of $\frac{2}{10}$ c.c. into the abdominal cavity. After the infection, which occurred twenty four hours later, all six animals remained healthy, while the unprotected mice died of tetanus in less than forty-eight hours. Therapeutic results may also be secured by the serum in the following manner: The animals are first infected by inoculation, and then the serum is injected into the abdominal cavity. Experiments with the serum were also made tending to show its great virus-destroying property. Of a ten days' tetanus culture, which had been made free of germs by filtration, .00005 c.c. sufficed to kill a mouse at the end of four to six days, and .0001 c.c. to kill in less than two days.

Now, we mixed .0001 c.c. of this culture and allowed the serum to act twenty-four hours upon the tetanus virus contained in the culture. Of this mixture, four mice received each 2 c.c. up to .033 c.c., or more than three hundred times the dose otherwise fatal to mice. Four mice remained permanently healthy, while the unprotected mice died at the end of thirty-six hours from .0001 c.c. of the culture. The mice, in all the hitherto-mentioned series of experiments, both those into whom abdominal cavity serum was injected, and those who were injected with a mixture of tetanus virus and serum, have remained permanently protected. They resisted subsequently repeated inoculations with virulent tetanus bacilli. This fact is especially noteworthy because in the innumerable individual experiments no mouse, no rabbit, in fact, no animal hitherto tested, had been found protected, and because the very long-continued attempts in the Hygienic Institute to make animals safe against tetanus by the hitherto known methods, have been entirely unsuccessful. The authors claim that they are justified in drawing the conclusion that the above expressed interpretation of the occurrence of immunity which at once, and without any difficulty shows a positively effective, and for the animals, entirely innocuous method of producing immunity, also satisfied the need of preventing its causation. As a matter of course, experiments were also made with the blood and serum of non-immune rabbits. This blood and serum proved therapeutically, as well as prophylactically, to have no influence upon the tetanus virus. This was also true of cow, calf, horse, and sheep serum, as was shown by special experiments. The blood within the vessels of living non-protected animals also possesses no tetanus destroying promises, as appeared from the following experiment which was repeatedly made:

Animals who received a subcutaneous injection of .5 c.c. of a virulent tetanus culture, free from germs, died after five to six days with typical symptoms of tetanus. At the autopsy, in almost every case, a serious transudation is found in the pleural cavity. Of this transudation .3 c.c. on the average suffices to produce tetanus in a mouse, and to kill the animal, and in the same dose the blood of a tetanus-poisoned animal again produces tetanus in mice. In conclusion, the authors express a hope that the principles demonstrated in these experiments may in time be applied to the treatment of diphtheria and tetanus in man.

Still Alive and Well.—Dr. Lassar, of Berlin, late Secretary-General of the International Medical Congress, sends us a letter denying the rumor that he has been ill, saying: "My state of health has always been a perfect one, and is so still. After finishing my duties at the International Congress, I made a long-projected trip to the United States of America, for which I had made arrangements with the White Star Line months before. After having taken a glance into your grand country, I returned in order to continue my duties as general secretary to the German Society of Naturalists and Physicians, whose latest 'Transactions' (September, 1890), edited by myself, I have the honor to forward you. As to the other rumors alluded to in your report, I only have to assure you that they are just of the same value as the foregoing, and luckily not at all founded on facts. I am very thankful for the sympathetic way in which you and your countrymen have acknowledged my modest services at the congress, and hope you will see your way to oblige me by publishing this letter. Believe me, dear sir, yours very truly."

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, November 7, 1890.

GEORGE L. PEABODY, M.D., PRESIDENT, IN THE CHAIR.

Fatal Purpura Hemorrhagica.—DR. HERMAN M. BIGGS presented the stomach of a man who had died of purpura hemorrhagica. He was fifty years of age, and was admitted to Bellevue Hospital with synovitis of the knee. After ten weeks' stay he was put on iodide of potassium, ten grains three times a day, continued a week. At the end of the week there developed a characteristic iodide eruption on the face. The iodide was then stopped and the eruption disappeared. At the end of another week the patient complained of headache for about twelve hours, very severe in type. During the night following, spots of purpura hemorrhagica formed in enormous numbers all over the body. They increased very much the next day, and the second day the patient began to have hemorrhages from the tongue and nose. The bleeding was very profuse and uncontrollable. After twenty-four or thirty-six hours he became very weak, and six days after the hemorrhages had commenced he died, with symptoms of internal hemorrhage. Before this he had passed tarry stools. There had been no elevation of the temperature.

At the autopsy the body was found covered everywhere with hemorrhagic spots, varying from a centimetre to three centimetres in diameter. There were hemorrhages into the pleura and pericardium, into the stomach, and throughout the small intestine. The lower portion of the ileum was filled with masses of blood, the mucous membrane infiltrated, and small hemorrhages existed in the peritoneum.

Some cases of purpura hemorrhagica had been reported as following the use of iodide of potassium, but it hardly seemed possible to the speaker that such small doses as ten grains three times a day, especially since an interval of a week had elapsed since its discontinuance, could have produced such intense hemorrhages as were present in this case.

Replying to Dr. Dana's interrogatory, he said there was no cirrhosis of the liver nor other abnormal condition than that which he had mentioned.

DR. J. D. BRYANT did not think there could have been any relation between the joint-lesion and the purpura hemorrhagica. He inquired more definitely what had been done to the joint.

DR. BIGGS said nothing whatever had been done except to produce counter-irritation. There was no compound lesion.

Idiosyncrasy to Drugs.—DR. A. B. BALL said it was generally recognized that drugs not ordinarily poisonous, yet producing a poisonous effect in individuals with an idiosyncrasy, might produce that effect not alone in large, but also in small doses. For instance, he had seen most intense symptoms of poison from a single one-grain dose of quinine. There resulted an eruption resembling scarlatina; there was so much swelling of the tongue as to cause it to protrude from the mouth. A like effect was produced after administering this small dose on three separate occasions. So also with persons who were easily poisoned by iodide of potassium, a small dose was as likely to produce the effect as a large one. He did not mean to suggest, however, that Dr. Biggs's case was one of this kind. He had had no such experience himself; besides, there was an interval of a whole week between the time when the administration of the iodide had ceased and when the purpuric eruption broke out, which would make him all the more unwilling to admit any relation of cause and effect. With regard to the smallness of the dose, however, he thought that did not argue especially against a poisonous effect of the iodide of potassium. In fact, he did not think ten grains was a small dose, although it would not produce a poisonous effect unless the individual showed an idiosyncrasy.

Looked Like Infection.—DR. FRANCIS DELAFIELD thought this case gave the very straightforward history of a class of cases of purpura which behaved like an infectious disease. Of course we were still very ignorant of what that infection was, yet a sufficient number of such cases had accumulated to enable us to say that they had nothing to do with accidental things like the taking of iodide of potassium. This patient evidently did not die of bleeding; he died of poisoning of some kind. He supposed all present had seen such cases, and that which struck one was that the appearance of the patient was that of a person who was suffering from the effects of a poison. Dr. Biggs had not mentioned making any cultivations.

DR. BIGGS said the autopsy was performed so long after death that it was not thought worth while to make cultivations.

DR. DELAFIELD added that evidently such was the direction in which we had to look for an explanation. The case reminded him of an exactly similar one. Of course they were not numerous, but they were very much alike when they did occur.

DR. BIGGS inquired of Dr. Delafield whether he thought any distinction could be made between cases which were associated with elevation of the temperature and those which were not.

DR. DELAFIELD replied, no. It was analogous to what one saw in other infectious diseases. For example, a patient might die with septic peritonitis and have very little high temperature. A high temperature did not necessarily go with poisoning in that way. Again, observe the difference in temperature between cases of ordinary tonsillitis and of diphtheritic tonsillitis. He remarked that at the last meeting of the Section on Practice at the Academy of Medicine Dr. Lockwood read a very good paper on the different forms of purpura, grouping the cases in an interesting way. Of course there were many different kinds of purpura, but the case which Dr. Biggs had reported seemed to be an example of an infectious disease, the nature of which had not yet been determined.

THE PRESIDENT could not see how the iodides could have produced the effect in this patient, yet with regard to the size of the doses he might say that persons who suffered unpleasantly from iodides would suffer more from small doses than from large ones. For instance, one in whom five grains would produce an unpleasant effect might take twenty grains very easily.

The Rheumatic and Gouty Diathesis as Manifested in Diseases of the Throat.—Dr. Beverley Robinson read a paper with this title. (See p. 621.)

DR. ANDREW H. SMITH thought the paper had covered the ground very fully. The position taken, which was to some extent modern, was corroborated by experience dating far back. It was well known that practitioners formerly employed in many cases of throat trouble or quinsy, guaiacum, the influence of the drug being, probably, in the same line as that pointed out by the reader.

Later on it was recognized that there was a sore-throat which was connected with habits of life likely to produce gout; a sore-throat which could not be relieved by local applications, but was most influenced by restricting the diet. A little later still, remedies were employed which were known to be beneficial in gouty or lithæmic cases. His personal experience coincided with that of the reader.

DR. A. ALEXANDER SMITH was decidedly in accord with the reader of the paper, so far as the view had been expressed that there was an association between the rheumatic and gouty diathesis and many throat affections. He followed this view in a therapeutic way, not alone in acute cases, but often also in those of a chronic nature. Sometimes when fearing that he accepted this view too emphatically, he tried other methods of treatment, but

was often obliged to resort at last to agents which would correct the rheumatic or gouty tendency before he could obtain success. He made it almost a routine practice in acute superficial inflammatory conditions of the mucous membrane of the throat to use anti-rheumatic agents, and it seemed to him with very decided success. He was not surprised to hear Dr. Robinson express himself as not at all satisfied with the application of astringent agents which were relied upon by many for the relief of these affections. It seemed to him that very often local treatment could only be directed to the use of certain soothing agents, especially those of a very mild kind; that real relief was to come from correcting the diathesis which underlay the condition. He must admit, however, that he was not always satisfied of having made a correct diagnosis of this association until he had tried treatment. It might not be so scientific to wait for the action of a therapeutic measure before making a diagnosis. It was somewhat in line with the use of quinine in certain irregular manifestations, and jumping at the conclusion, should it prove beneficial, that the trouble was miasmatic.

Tonsillitis and Bad Drainage.—Dr. Biggs said the reference made by the author to cases of tonsillitis and rheumatism associated with bad drainage and unsanitary surroundings, reminded him of an interesting epidemic of tonsillitis which came directly under his observation the past summer while in the Adirondacks. Nearly every person in the hotel was taken with an acute follicular tonsillitis. On examination it was found that the water-closet, a large vault, had not been cleaned for many months. After cleaning it there was immediate disappearance of the tonsillitis.

Dr. Robinson said he had been led to write this paper because he believed there were many persons who suffered a great deal from trouble in their throats, and who spent much time and money in consulting specialists and general physicians without obtaining relief because the underlying condition was not recognized. Two cases were referred to as examples. A man had suffered any amount of pain in the throat, had passed through the hands of specialists without any relief, and finally came under the care of the speaker, yet, failing to recognize the true cause, of which there were no other manifestations, he did not succeed in giving the patient any relief. He then had him consult a distinguished specialist, with the hope that something might be found which he had overlooked, and this specialist told him that the turbinated bones were enlarged, and suggested an operation. Before this was undertaken Dr. Robinson gave the man colchicum and thus relieved the symptoms. The other case was that of a woman, whom some of the members had seen just before the meeting. She had been under his care for two years. There were rheumatic manifestations and swelling of the joints at times, from which relief was obtained by salicylate of soda. At other times she suffered from trouble in the throat, and less from the joint affection, yet anti-rheumatic treatment best relieved the throat difficulty.

Dr. C. L. Dana remarked that Dr. Robinson had referred to three diathetic conditions, the rheumatic, the gouty, and the lithæmic; he would ask whether he recognized any throat disorders due to a diathesis besides the rheumatic or gouty.

Dr. Robinson feared he had made himself misunderstood. Perhaps he should not have called the lithæmic condition a diathesis. There was a lithæmia which he believed was due to bad habits, as drinking or eating too much, and which would disappear with the correction of those habits. On the other hand, he believed there was such a condition as the rheumatic and the gouty diathesis. Sometimes they were very distinct, while at other times it was hard to distinguish between the two. Nor would an examination of the urine enable one to make the differential diagnosis. More reliance could be placed upon the effect of remedies in making the diagnosis in these cases than upon the symptoms.

Regarding Mineral Waters.—He would like an expression of opinion with regard to the value of certain mineral waters in these cases. Judging from his limited experience he thought these patients were no better for drinking Richfield Springs or Sharon waters. The bath and the spray did good, but he was not at all confident that drinking the water was of any benefit. Perhaps it was because of the salts of lime which the waters contained.

The President asked if it was not a fallacy to suppose that drinking sulphur water any place whatever was of service in joint troubles. Moreover, he thought the benefit derived on using sulphur baths was due largely to the influence of the heat, the change of air, and freedom from care.

Dr. Andrew H. Smith asked the President whether sulphur had not a diuretic effect.

The President doubted whether sulphur water had any more diuretic effect than had simple water.

Dr. Andrew H. Smith remarked that inasmuch as the internal use of waters usually went hand in hand with the external use, it was difficult to say to what form the benefit should be ascribed.

Dr. Dana thought sulphur had no effect on rheumatic joints when taken internally, and the President coincided in this view.

Dr. Clement Cleveland asked the President whether he was to be understood as saying that alkaline hot baths were useful only because of the heat.

The President replied that he thought the efficacy of baths was almost uniformly in proportion to the heat applied. There might be some mineral ingredient which produced a certain amount of counter-irritant effect apart from the heat, but that was uncommon, and as a rule the baths were beneficial in proportion to the amount and continuance of the heat. That there was no absorption of the mineral, with few exceptions, he thought could readily be proven. In fact he thought the fallacy with regard to the efficacy of mineral baths was very great.

Dr. Robinson thought he had seen rheumatic joints made less painful by the use of hot water combined with potash salts, notably bicarbonate of potash, more than by hot water alone.

Dr. Andrew H. Smith was in the habit, when the joints remained swollen and stiff, though not positively painful, following rheumatism in which salicylates had done all the good they were capable of, of having them soaked in an alkaline solution, and he thought with benefit above that coming from the heat alone.

The President said he applied heat alone in the form of poultices or hot compresses, having abandoned mineral ingredients, and he thought his results were just as good as formerly when mineral ingredients were present.

The Soda Bath in Rheumatism.—Dr. Cleveland said that twenty years ago, when he was interne at Charity Hospital, all cases of acute rheumatism were put into the soda bath, with a temperature of 105° F. The patients remained in the bath ten or fifteen minutes, unless there was some positive effect on the heart's action. Usually after two or three baths they were quite cured of the attack, no internal remedies being administered. He had treated the few cases which he had seen since in the same manner, with very satisfactory results.

In a Bath Six Months.—Dr. A. H. Smith remarked, as bearing on the question of absorption of simple water during a bath, that while in Hamburg the past summer he saw patients who had been kept in the bath for weeks, and even six months, yet it was stated that they had the same degree of thirst as under ordinary conditions.

The President remarked that the outer layers of the skin would absorb water and the epidermis become somewhat softer and thicker, but that the water reached the blood-vessels he thought had been distinctly disproven. Replying to an interrogatory by Dr. Bryant, he said he thought density had no influence.

Peculiar Skin Eruption.—Dr. Andrew H. Smith related a case of peculiar eruption on the skin seen in the Presbyterian Hospital some days since. The patient was an Italian man, who was brought to the hospital, although there was no elevation of the temperature, nor feeling of illness. Nearly the entire surface of the body, however, was covered with what seemed to be very minute pustules. They were very superficial, scarcely reaching beneath the superficial layer of the epidermis; were white, and like the surface of a nutmeg-grater. He was given a good scrubbing, and a large proportion of the pimples were brushed away, leaving slight abrasions. In a day or two scarcely any were left. There were no constitutional symptoms whatever. He made careful inquiry as to the use of any application, but none had been employed. The appearance was somewhat like that following the use of croton-oil, but without the presence of dermatitis.

The President said some proprietary preparations containing a small amount of croton-oil would have that effect.

Dr. George F. Shrady referred to a case in which a similar eruption appeared on the face, neck, hands, and arms in a woman who had used a proprietary preparation containing a strong alkali, to which the eruption was attributed. She made it the basis of a suit for damages.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual Meeting, November 24, 1890.

Report of the Editor of the Medical Directory.—Dr. A. S. Hunter, the retiring President, called the adjourned annual meeting to order, and the Society first listened to the report of the editor of the Medical Directory, Dr. Daniel Lewis. He stated that the Directory was steadily gaining in circulation outside the Society. Nearly two thousand copies had been distributed. The receipts from sales, advertisements, etc., had been $1,333.60; expenditures, $1,145.21. One thing which the Society had gained by publishing the Directory was the payment of nearly seven hundred dollars back dues by those who wished to have their names retained in the published list of members. The report was accepted.

Providing for the Current Year.—Dr. John S. Warren offered the following: Resolved that the comitia minora be authorized to expend during the coming year such an amount from the funds of the Society as it deems necessary for its successful management. Adopted.

Address of the Retiring President.—Dr. Hunter, before turning the office over to his successor, read a brief address, in which he said the Society had listened during the two years of his presidency to the reading of twenty papers, especially prepared to meet the wants of the general practitioner. The strength and usefulness of the Society was steadily increasing. In our new quarters we would find a comfortable, convenient, and roomy home. In the new building of the Academy there was plenty of space to introduce a new feature, which, if adopted, would not only largely increase the attendance, but also serve to still further unify our membership. He referred to the advantages which would accrue from a simple collation after each meeting. The feasibility of such a feature had been presented to the comitia minora months ago, and had received their unanimous approval. He suggested the exclusion of wine and beer, and that those who wished to smoke bring their own cigars.

He thought power to deal more effectually with the more brazen medical frauds in the community would come with the new law requiring the licensing of practitioners by the regents of the university.

Address of the Incoming President.—Dr. Orlando B. Douglas, President elect, then took the chair, and read an address, in which, after expressing gratitude for the honor conferred upon him, he reviewed some of the more important points connected with the founding of the Society and its subsequent growth. The facts went to show the advantages of medical association in the upbuilding of medical science and art, and in putting down quackery. The names of some of the founders of the Society in 1806 were permanent in the annals of the country. There had been forty-nine presidents of the County Society, the senior living ex-president being Dr. Samuel T. Hubbard, who had, at his invitation, taken a seat upon the platform. He was a good illustration of the statement, that it was better to be young at seventy than old at forty.

Committees.—Dr. Douglas then appointed the following committees: *On Ethics*—Mark Blumenthal (chairman), J. Leonard Corning, and Wendell C. Phillips (two more to be appointed). *On Hygiene*—Abraham Jacobi (chairman), Henry D. Chapin, H. P. Loomis (two yet to be appointed). *On Prize Essays*—Andrew H. Smith (chairman), Simon Baruch, and Andrew F. Currier. *Auditing Committee*—William Stevens and Robert Campbell.

On motion the question of having a collation after the meetings was referred to the comitia minora with power.

On motion the old committee on hygiene was requested to make a supplementary report, in order that that part referring to the condition of the public schools might be brought before the Board of Education without having to wait the usual time required for submitting the report to the State Medical Society.

The Resorption of Immature Cataract by Manipulation Conjoined with Instillation.—Dr. Richard Kalish read the scientific paper of the evening, bearing this title, which will appear later in these columns.

Sceptical.—Dr. H. D. Noyes said the subject was one of a good deal of interest, for it appealed to the happiness of a large number of people. He would have been better pleased with the paper had it been presented with more direct relation to the pathology of cataract. Cataract was not a single form of pathological condition of the lens. It had very multiform relations. He had hoped on reading the announcement of the meeting that the author would state the kind of cataract which he deemed suitable and the kind which he deemed unsuitable for this treatment. Instead of that, he had stated that his treatment of cases had been invariably and permanently successful. Being again assured by the reader of the paper that he had not misunderstood him, Dr. Noyes went on to say that he regretted to have to mention a case which the reader had apparently forgotten, a case in which he had treated the patient in this manner, she did not improve, and later a cataract operation was performed by another surgeon.

The cases illustrated upon the screen had all been of one type; they were cataracts in which the lens presented diffuse cloudiness. One did not observe, except in one case, marked striation. One who had had much experience in opthalmology must have had plenty of opportunities to correct his early mistakes in prognosis. He had put down upon his books many times the opinions of his patients which in the future they changed.

One case was illustrative of others of a certain kind, that of a lady whom he was treating with glasses for a condition of the eyes, and he noticed cataract striæ in the periphery of the lens, but declined to inform her of the fact because of her nervous disposition. Seven years afterward he saw her again, and still discovered the same striæ without further change in the lens.

To make himself more clearly understood, Dr. Noyes spoke briefly of the pathology of cataract. In senile cataract there was sclerosis of the nucleus of the lens, the lens growing harder as age progressed, most marked in the nucleus. In certain persons this hardening process went on in such a fashion that the nucleus hardened at a rate considerably faster than the cortex, the result of which was that clefts and fissures formed in the cortical portion, and it was these fissures which were seen as striæ. They were, in reality, open spaces which, as they

were formed, became immediately filled with fluid. The fluid was more or less serous in character, but became albuminate. It was liable to degenerate, and produce more or less degeneration in the fibres of the lens. Then again the process might take place rapidly and the lens swell. He had for many years told certain classes of patients that he might be able to do something for them, and that in the course of a few months they would be able to see better. He had made that observation many times, and what did it mean? It meant that the serous fluid which had become effused into the substance of the lens, between its fibres, gradually became spontaneously absorbed, the lens adjusted itself to the new condition, became more homogeneous, somewhat more dense, and thereby vision was made better; there was less disturbance in the refraction of light passing through. Another result was some impairment of the nutritive source of the lens, the blood-vessels in the ciliary region. When opacity existed in the lens it was extremely common to find opacity in the vitreous humor. It was so frequent that he had many times given small doses of iodide of potassium and in a few months seen marked improvement in vision while at the same time little change could be observed in the condition of the lens.

Dr. Noyes then analyzed the cases which Dr. Kalish had reported in his first paper, with a view to seeing whether the apparent improvement could not be accounted for in some other way than by the treatment. He thought that the recorded history by no means justified the statements made by the author regarding the value of his procedure. He hoped he would place himself in an attitude where he would not be subject to criticism based on incomplete observations, or leaving unsaid that which it was necessary to say in order to establish such remarkable claims for this mode of treatment. He also thought it only fair that he should permit experts in his own department to examine some cases before and during the treatment.

Dr. Herman Knapp had listened with intense interest to the paper, for the announcement that cataract could be absorbed had filled him with diffidence if not with scepticism. It did not, however, seem unreasonable that cataract might be absorbed. There was no decay of fibre, there was scarcely anything which distinguished the cataractous lens from the normal lens, and therefore it was not astonishing that since time immemorial attempts had been made to cure cataract without resorting to the knife. These attempts dated back two thousand years, and still every two or three years a new remedy for cataract was published in the secular and medical press, and had a certain run. He was far from disbelieving the reports of Dr. Kalish, but he wished to understand them; he wanted to know with what kind of cases he had had to deal. He had been impressed by the fact that of the different drawings which he had seen, not one was of regular cataract; all were more or less irregular opacities in the pupillary area. He would call them anomalous cataracts. Opacities of the lens should be called cataract only when really progressing, and when in that condition in which ophthalmologists generally regarded them as incurable except by an operation. Then he hoped the author would publish the names of his patients, or so designate them that if they subsequently came under the observation of other surgeons they would be known. The results of cataract operations were far less uniformly good than the author had claimed for his method.

Regarding the case of ripe cataract, the patient seeing twenty-six inches after treatment, he had seen such patients improve to such a degree after there came out of the diffuse opacity one uniform amber-colored substance, the lens being left nicely rounded, that the patient could see fingers not only twenty-six inches, but even twenty feet.

But the paper had chiefly to do with incipient cataract. Cataract, he said, was certainly a disease, and in its incipiency was almost invariably connected with opacities of the vitreous. These changes were transient. He thought it could be said there were some changes in the crystalline lens produced by this condition giving rise to opacities of the vitreous, the changes in the lens forming cataract—in some cases progressing, but in numbers of cases not progressing, but even improving subsequently. He knew such cases by the hundred. He treated them by regulating the diet, not permitting use of the eyes at night, and by general methods. It was known that at sixty years of age thirty-three per cent. of the population had incipient cataract, not progressive; that at seventy, sixty-six per cent. had cataract, not all progressive.

The Question of Priority.—Dr. Knapp also asked the author about the originality of his method; as he understood the two methods, this was much like that used by Dr. Roth, of Boston, who practised manipulation and used some liquid. Some of his patients went to Dr. Roth, and came back saying they were much improved, but many of them came again later for an operation. He closed by repeating that he thought it was not irrational to treat cataract with the idea of producing absorption, but he thought the success of the method lacked satisfactory proof.

Dr. David Webster had had to tell patients inquiring about the method that he thought it yet lacked proof. He did not doubt the honesty of the reporter this evening, but he believed some allowance would have to be made for enthusiasm, both on his own part and that of his patients. Two treated by Dr. Kalish had been seen by him; one expressed the view that he thought his vision had been somewhat improved, the other was positive of it. But six months, or even a year, was not sufficient time to establish the permanency of the result. As other speakers had just said, many cases of cataract did not progress, though not treated.

Dr. Bucklin said he had seen changes in the lens as great as those shown on the screen even without treatment. He thought the method of Dr. Kalish was like that of Dr. Roth.

Dr. Kalish said, with reference to the case which he was supposed to have forgotten, that he did not include it among his cases because the woman was in poor health, unsuitable for the treatment, and he undertook it two or three sittings only at the urgent request of her daughter, and gave her three or four other such sittings as would satisfy her something was being done.

So far as attributing all his results to absorption of serous effusion was concerned, it seemed to him strange that all his cases should have had that serous effusion. His cases were all benefited, and they presented different varieties of cortical opacities. He certainly believed from the histories that the cataract was advancing; there was gradual diminution in sight in all, and in most of the cases cataract had been diagnosticated by other opthalmologists. So far as opacities of the vitreous were concerned, he had not considered them in speaking of results, simply for the reason that he had not been treating vitreous opacities; he had been treating opacities distinctly in the lens. His tests had been repeated under the same conditions as nearly as possible. As to patients with incipient cataract getting better spontaneously, he did not know that they always did so, while he did know that they uniformly got better under his treatment. He had known nothing about Roth's treatment when he began his method; besides, he understood Roth's manipulations were very different, and as to his fluid, while its exact composition was not known, yet some of his patients had told the speaker it had a different effect, was more irritating, and looked different from his own mixture of glycerine, boric acid, and rose water.

The President announced, papers for the next meeting by Dr. Rockwell, on the different physiological and therapeutic properties of induced currents of electricity with especial reference to bipolar faradization; and by Dr. Phillips, on some points in local therapeutics in diseases of the nose and throat.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, November 17, 1890.

S. B. WYLIE MCLEOD, M.D., VICE-PRESIDENT, IN THE CHAIR.

Appendicitis, Typhlitis, and Perityphlitis in Children.—Dr. J. LEWIS SMITH read a paper on this subject. He spoke first of the structure and relations of the parts affected in these inflammations, and those of the period of childhood at which they were most liable to occur. Matterstock had collated 72 cases; and of these 2 were under the age of two years, 10 between the second and fifth year, 25 between the fifth and tenth years, and 35 between the tenth and fifteenth years.

As to the etiology, he said that the most common cause was the lodgment and impaction in the cæcum or appendix, or both, of fecal matter, or hard, indigestible bodies, which produce inflammation, and sometimes perforation by their pressure. In 49 cases of fatal perityphlitis embraced in Matterstock's statistics perforation had occurred in 37; from which it might be inferred that in the majority of cases of perityphlitis resulting from appendicitis perforation of the appendix had occurred. In the analysis of 152 cases collated by Fitz the result was very similar to that noted by Matterstock. The fecal concretions found in the appendix were single or multiple, and of different degrees of hardness.

In speaking of the anatomical characters he said that in children the initial lesions, with few exceptions, occurred in the appendix. Atrophy or necrosis of its epithelium took place from pressure of the foreign substance. Then the intestinal microbes invaded the exposed sub-epithelial tissue, causing septic inflammation, which extended through the muscular coat to the sub-peritoneal tissue and to the peritoneum, causing a local peritonitis. Or it ceased before reaching the peritoneum, producing gangrene or ulceration of the underlying tissues, and, as they contracted in healing, the lumen of the appendix might be obliterated and its shape changed. Sometimes the appendix was nearly or quite obliterated, its place being occupied by cicatricial tissue; or its proximal end might be obliterated while its distal end remained open. A retention cyst then resulted, which might subsequently be inflamed, and might at some point be destroyed by gangrene or ulceration, so that its contents escaped, causing peritonitis. Occasionally similar changes occurred in the cæcum. In the mild and favorable cases of perityphlitis a fibrinous exudation occurred over the inflamed parts, so as to limit the extension of disease and prevent the escape of pus or fecal matter.

Balzer stated that perityphlitic abscess was much less frequent in children than in adults. The location of such an abscess depended on the place of perforation. It was said that in most instances the centre of the abscess was behind or alongside of the cæcum, and if it extended upward, its walls consisted of intestine and the posterior and lateral parieties of the abdomen. The abscess, left to itself, might open in any direction, with symptoms varying according to the direction taken. Evacuation of the pus per rectum had been regarded as favorable from the time of Dupuytren. But the result was not always favorable when the abscess broke into the intestine; for, after the pus had been evacuated, fecal matter might escape through the opening, carrying with it microbes which might poison the system and set up septic fever. Extension of the inflammation from the perforated appendix to and around the contiguous blood-vessels might cause disastrous results.

While perforation of the appendix commonly resulted in localized peritonitis, a more serious and ordinarily fatal result sometimes followed, viz., the occurrence of acute diffuse peritonitis. This might take place immediately after the perforation. Frequently, however, an abscess formed, perhaps of little extent, around the appendix, and it might continue for weeks or months without producing any dangerous symptoms. Finally it burst, and its contents escaped into the general peritoneal cavity, producing an acute peritonitis which rapidly extended over the peritoneal surface. A large proportion of the cases of perforation of the appendix, if left to themselves, terminated after a time in this manner, in peritonitis, which, from its extent and severity, was usually fatal.

In reading the paper, Dr. Smith omitted the portion detailing the symptoms, and went on to speak of the matter of diagnosis. Recurring pain or tenderness in the right inguinal or lumbar region at intervals of a few weeks, he said, should excite suspicion of the presence of a foreign substance in the appendix. Sometimes the accumulation of fecal matter in the cæcum could be determined by palpation. The diagnosis from invagination was not difficult, since the latter occurred chiefly in infancy, was attended by a tumor more centrally located, and was often accompanied with bloody stools and fecal vomiting. Perityphlitis had sometimes been mistaken for hip disease; but the swelling in the latter was lower down, and in perityphlitic induration the characteristic signs of disease of the hip-joint were absent. Dr. Smith also referred to Senn's hydrogen-gas test for perforation and to the diagnosis between perityphlitis and psoas abscess.

The prognosis varied greatly in different cases. If the inflammation were of little extent and encapsulated, and sepsis did not occur, the prognosis was good. On the other hand, if the perforation of the cæcum or appendix were of considerable size, with the escape of much feculent matter, the inflammation which resulted in the peritoneum or retro-peritoneal tissue, with perhaps consecutive septic inflammation in adjacent organs or tissues, was almost certain to terminate fatally. It was evident that the statistics relating to the result, as given by different writers, varied according to the extent and severity of the disease in the cases which they had collated. Having mentioned the relative number of deaths and recoveries published by various authors, he said that according to Matterstock age influences the result in a measure, since of 12 patients under the age of six years, 11 died; of 24 between the ages of six and ten, 15 died; and of 34 between the ages of ten and fifteen, 23 died. Diffuse peritonitis was usually fatal, while evacuation of the abscess into the cæcum or rectum generally justified a favorable prognosis. Evacuation of pus through the abdominal walls, if it took place at an early date, was also regarded as favorable. Laparotomy and evacuation of the pus through the abdominal walls, if performed at the proper time, and with antiseptic precautions, increased the chances of recovery. In those mild cases in which the inflammation was of slight extent, and the patient was soon convalescent, a sudden aggravation of symptoms sometimes occurred from breaking loose of the inflammatory products, and the case ended fatally.

Dr. Smith spoke first of prophylactic and then of curative treatment. In dealing with the latter he referred particularly to the plan of Professor Henoch, of Berlin, who keeps the intestines perfectly quiet by opium, and only gives castor oil or calomel when prolonged constipation and palpation indicate the presence of a large fecal accumulation in the cæcum. Otherwise, he abstains from purgatives. He applies a few leeches, without after-bleeding; if there be much tenderness, gives an emulsion of oil with the aqueous extract of opium every two hours, and uses constantly the ice-bag over the cæcum. When with this the pain and tenderness cease, it is found that defecation usually occurs spontaneously or can be produced by a simple enema or a dose of oil. Henoch has made the following remarkable statement, which, were it not for his well-known accuracy and high professional standing, might be thought to be an exaggeration: "When this treatment was begun early enough, recovery ensued in almost all cases, and if a swelling had been formed by the exudation, its transition into suppuration

was prevented even in children who, in the course of a few years, had been repeatedly admitted to the hospital on account of relapses."

Dr. Smith thought that Henoch's treatment was probably the best that could be adopted before the stage of suppuration. The use of laxatives, even of laxative enemata, he said, should be postponed until the tenderness and other inflammatory symptoms had to a considerable extent abated by the use of opium and the ice-bag. If, then, the presence of fecal masses were ascertained by palpation, a large clyster of warm water containing one ounce each of glycerine and sweet oil, might be given, or perhaps, as recommended by Henoch, a dose by the mouth of castor-oil or calomel. Even at the commencement of the treatment Dr. Smith thought it proper to employ such a clyster as that mentioned if there were a history of constipation, and if on palpation the cæcum appeared to be distended with fecal matter. The diet should consist of liquids which leave little residuum, such as the beef peptones and peptonized milk. Carbolized water might be allowed to relieve thirst or nausea. If the case resulted favorably without surgical interference, the child should lead a quiet life, avoiding violent exercise for a considerable time, on account of the danger of relapse.

If the inflammation continued and a perityphlitic abscess formed, this required opening. In 1882 Dr. R. F. Noyes collated the records of one hundred and nineteen cases in which an operation was performed, only about sixteen per cent. of which proved fatal. The late Dr. H. B. Sands strongly objected to the use of the exploratory needle at an early stage of the inflammation, since it might penetrate the healthy peritoneal cavity and pierce the intestine, and if the instrument entered the abscess the foul substance adhering to it would probably infect the peritoneum and cause diffuse peritonitis. Morton stated that the aspirator needle should never be used, and Ransohoff also objected to it. G. Buck, Weir, Noyes, and Bull advised, if the presence of pus were determined by the needle, to leave the latter *in situ* to serve as a guide in making the incision.

After referring to the various incisions practised by different surgeons, he said that laparotomy had been performed many times during the last ten years, and cases had been published showing very favorable results. Still, it was not to be forgotten that the favorable cases were much more likely to be reported than the unfavorable ones. Having described successful cases reported by Drs. Sands and Homans, he went on to say that such cases show what may be accomplished by surgical treatment even in cases where diffuse peritonitis has resulted. Of course, however, when peritonitis not limited by adhesions occurred, death would result in a considerable proportion of cases under any treatment whatsoever.

Removal of the perforated and diseased appendix, when it could be readily brought into view, was now generally recommended by surgical writers, since the diseased appendix was a source of irritation, and by the subsequent escape of fecal matter it might cause a renewal of the inflammation. But in a large proportion of cases the appendix lay at the bottom of the cavity, surrounded by adhesions, so that it could not be removed without considerable cutting and tearing of the parts surrounding it, and perhaps producing an opening through which inflammatory products might escape into the peritoneal cavity. In regard to the surgical treatment of perityphlitis and the perityphlitic abscess, however, he thought the surgeon was more competent to express an opinion than the physician.

Dr. Edward G. Janeway said he only desired to direct attention to a few practical points, and especially in reference to the question how far liable are we to make mistakes in diagnosis. He then proceeded to enumerate some of the conditions which were liable to be sometimes mistaken for appendicitis or perityphlitis, and *vice versa*. Among them were the following: Neuralgias affecting the right iliac region and adjacent parts. In making the differential diagnosis an important point was to ascertain whether the tenderness was located superficially or in the deeper tissues.

Renal Colic.—The pressure produced by appendicitis was sometimes liable to cause pain in the region of the right kidney, and this was especially the case if the abscess became situated down between the rectum and bladder. Here it was of service to make deep pressure in the seat of the appendix.

Fecal Impaction.—He had met with two cases of this in children where the question of appendicitis arose.

Inflammation of the mucous membrane, in certain rare cases without any impaction or induration. The way in which the symptoms come on, however, if the cases are investigated carefully, would generally show that we had to deal merely with a case of catarrhal enteritis especially affecting the colon. The diagnosis would also be established by the prompt subsidence of the trouble.

Carcinoma of the Cæcum.—This, of course, was only met with in adults, and was a rare condition. Pelvic cellulitis and peritonitis in young girls as well as women. Many such case were doubtful when the physician was debarred from making a vaginal examination. Reflected pains, as from pleurisy and pneumonia. The earlier stages of certain cases of typhoid fever. Lumbar abscess from caries of the vertebræ. Subphrenic pneumo-hydrothorax.

While the diagnosis was usually very easy, in some instances it was extremely difficult. As to the matter of operation, he thought that there was not a sufficiently strong line drawn between the cases in which general peritonitis occurs at the outset and those in which the trouble is strictly localized. In the former class the patients almost invariably did badly. A question of far more importance was this: If we have appendicitis with induration, is peritonitis likely to result? It was often a difficult matter to decide whether to operate or not. He supposed, however, that it was probably the wisest course to open the abdomen in all cases where appendicitis is followed by peritonitis. In regard to abscess, the abscess should be opened at the earliest moment after a purulent accumulation is discovered. As to exploration with the hypodermic needle, it seemed to him that such a procedure was absolutely injurious unless practised with special precautions. It should only be resorted to, he believed, with the child under ether and as a prelude to incision. To make such an exploration and then not do anything for, say twenty-four hours, was a course that could not be too strongly condemned.

Dr. Charles McBurney said he was sorry to see that Dr. Smith still adhered to the terms perityphlitis and paratyphlitis. It was liable to lead to confusion by giving rise to the idea that that there were quite a number of diseases which produced the condition in question, when as a matter of fact the appendix was almost invariably the seat of the original trouble; the cases in which this was not so being extremely rare. He agreed with Dr. Janeway that the most interesting and important question to be considered was the one of arriving at a correct diagnosis at the earliest possible moment. In his opinion the physician and the surgeon should study each case together from the very beginning of the attack. The surgeon was very commonly called in at too late a time, when operation could only result in failure, and as an illustration he narrated a case in which he was asked to operate after the attack had lasted six days, general septic peritonitis had set in, and the patient was already in a state of collapse.

The early localized signs were of great importance, and if we hoped to save our cases it was generally necessary that we should decide within the first twenty-four hours whether to operate or not. He had no desire to operate in cases which did not require surgical interference, and therefore he was especially interested in the matter of early diagnosis in the different varieties of cases

that were met with. The operation (by which he meant the opening of the abdomen in order to make a diagnosis) was certainly not a very severe or dangerous one. One very noticeable point was the fact that even in a large number of cases where a deliberate laparotomy was performed and a considerable amount of manipulation was required, he did not know of a single instance in which septic peritonitis had resulted from the operation. The mortality from the operation was very slight, and the percentage of deaths, as shown by the statistics, was certainly very much less in those cases operated on at the proper time than in those in which either no operation was performed or it was resorted to at too late a period. We were often told that we must wait till signs of septic peritonitis had occurred; but what course could be more dangerous than this, when the very object of operating was to prevent peritonitis? As to the signs of impending perforation, which we were also told to wait for, he did not know what these signs were, and should very much like to be informed.

As to some of the results obtained from operating in the early stages, Dr. L. A. Stimson had reported five cases without a single death. His own cases amounted to twenty, and all had recovered but one. The fatal result in this case was caused by paresis of the entire intestine, and he was convinced that this was due to too long delay in operating. Such results are certainly better than those given in the statistics quoted by Dr. Smith. If the patients who were not operated on did not have septic peritonitis, they were liable to suffer in other ways. The appendicitis was apt to go on to abscess, and he knew of two cases in which when relapses occurred there was extensive burrowing of pus. If the appendix were removed by operation the patient was saved all future trouble of this kind. The thing that he most feared in connection with appendicitis was the allowing of a case which ought to be operated on early to go on too long without interference.

Dr. Charles A. Leale narrated a case of abscess in which he had operated successfully under very discouraging circumstances. He thought the use of the exploring needle could not be too emphatically condemned. In addition to other evils, it was apt to increase the peristaltic action of the intestines, and sepsis was liable to result. Surgeons sometimes said it was too late to operate, but he thought it was never too late to operate. As an illustration he referred to a case which occurred many years ago, in which Dr. Willard Parker and several other surgeons were called in consultation, and the result of the consultation was that an operation would be hopeless, and should not therefore be attempted. Afterward the family sent for Dr. Parker alone, and asked him to operate. He did so, and as a result of this procedure the patient was alive to-day. If there was one chance in a hundred for the patient, he thought that he ought to be given this chance.

Dr. McBurney having been asked by Dr. Oberndorfer upon what signs he would rely in deciding the question of whether to operate or not, stated that this was a matter in regard to which it was practically impossible as yet to lay down any definite rules. In general he would say, however, that if he found a patient who had pain in the right iliac region, but with no fever, vomiting, or special interference with any function, and who looked well and was able to move about in bed with comparative ease, he would feel quite satisfied to let such a patient go on to the next day. If, however, the next morning he found that the tenderness had increased to a marked degree, that there was inability to move the part, that there was a well-defined point of exquisite sensitiveness, and that the temperature was over 100° F., he said he should tell such a patient that by an operation for the removal of the cause of his trouble he could almost certainly cure him and prevent the recurrence of anything of the kind in the future; while if the operation was not done, he would be likely to die of septic peritonitis, and if this did not occur an abscess would probably result, and he would be liable to dangerous relapses from time to time.

There were other cases which were very grave from the first. There would naturally be no tumor thus early, but extraordinary tension of the abdominal muscles on the right side would be found. There would be rapidly increasing tenderness and marked constitutional disturbance. Such cases he would not leave a single hour unoperated on. Dr. McBurney said he laid considerable stress on the amount of constitutional disturbance. The temperature, however, was often not at all high, and in some of the worst cases it was not above normal.

Dr. Smith, in closing the discussion, spoke first of the difficulty in making an early diagnosis in many of the cases. The seat of pain, as Dr. Janeway had remarked, was often deceptive, and he had met with one instance in which it was principally located in the upper part of the lumbar region, and another where the pain was in the situation of the right kidney. As to the desirableness of calling in a surgeon on the first day, he was not entirely prepared to accept Dr. McBurney's opinion, and very few families, he thought, would be willing to consent to such a course. The surgeon would be almost sure to advise laparotomy, and when so eminent an authority as Henoch had made the statement that when the opium and ice bag treatment was begun early enough, recovery followed in almost all cases, he did not think that such a measure was called for in the early stages.

Inoculations for Pulmonary Tuberculosis.—Dr. H. J. Boldt made a few remarks on this subject, his object being to call attention to the work in this direction which had been accomplished by a member-elect of the Association, Dr. J. Hilgard Tyndale. For many years he had been pursuing experimental investigations upon the subject, and for the past year and a half he had met with excellent results from the inoculation of bovine virus diluted in a saline solution. Among the results noted in tuberculous patients were the following: The bacilli decreased in the sputa, hectic disappeared, cough diminished very rapidly, the weight increased, and the health generally improved. As in the case of Koch's inoculations, the constitutional symptoms after the inoculation were quite severe. Dr. Boldt felt sure that Dr. Tyndale would be very glad to explain his process and to exhibit some of his cases to any members of the Association who might be interested in the matter.

THE SOUTHWESTERN OHIO MEDICAL SOCIETY.

Regular Semiannual Session, held at Cincinnati, October 16 and 17, 1890.

The President, J. C. Reeve, M.D., of Dayton, in the Chair.

Typhoid Fever and Tuberculosis.—Dr. J. T. Whittaker, of Cincinnati, said: "Typhoid fever we know now to arise wholly and exclusively from drinking-water contaminated with the fæces of typhoid-fever patients. We get it, plainly, in our city from infected river water, and the lesson we are taught every year cries louder than the water famine of a single year for reformation in this regard. Nature has kindly lifted for us, in our immediate vicinity, great natural basins for reservoirs on the adjoining hills of Kentucky, above cities which are in reality but suburbs of our own, across a river which will soon be bridged at every block, and all that is needed is pumping stations higher up the river, at sources of more pure supply. From large receiving basins on the Kentucky shore, wherein the water might remain a week or more to settle, the streams may be conducted over a viaduct to our present basins as centres of distribution. The typhoid bacillus does not live long in fresh water, according to recent investigations not longer than a week, and whatever germs of disease are present would gravi-

tate to the bottom of the lake if quiescent, to be removed with other refuse when the basin is cleared out and cleaned. The objection of the ward politician, that our sister State might some day be an enemy, is easily met by the preservation of our present works for such a dire emergency.

"Tuberculosis we have always with us, as a result, almost wholly and solely, of contamination of the air by dried disseminated sputum. The spectre of heredity has now disappeared entirely from the etiology of this disease, with the observation that the children of tuberculous parents removed from danger of infection entirely escape the disease. Advanced tuberculosis in parents never produces the disease in the new-born, for the simple reason that the essential elements of a fecundation never show or contain the tubercle bacillus. This disease is not congenital, but contracted, acquired after birth by breathing in an infected air. All that is necessary to prevent the dissemination of this disease is to keep the sputum moist, to use cuspidors and cups half-filled with water, to be emptied daily in drains, which in turn empty in running streams. No particulate bodies can possibly arise from moist surfaces. This particular simple law contains all the essence of prevention in the case of this disease."

Dr. Whittaker next described the various agents used to limit the growth of the bacillus in the body of man, and made mention of the recent discoveries of Koch with the cyanide of gold, and more especially with the salts of cobalt, which would prevent the inoculation of the extremely sensitive guinea pig, or check the advance of the disease in animals inoculated before. Every clinician and every pathologist believed that the time was near at hand when some agent would be found to destroy, or, more especially, to check the growth of the tubercle bacillus in the body, without damage to the cells and tissues of the body. The doctor did not believe the recent telegraphic despatches to the effect that Koch had abandoned his experiments concerning the cure of tuberculosis.

Peritonitis.—Dr. Dan Milliken, of Hamilton, laid special stress on the symptoms, a very pointed one being pain. The patient lies on his back, with knees elevated and soles of feet applied to the bed. This is done to prevent the bedding from touching the exquisitely tender abdomen. Abdominal respiration is abandoned, and shallow respiration takes its place. If there be any cough, the patient makes every effort to suppress it, on account of the severe pain it causes. Vomiting is an early symptom, and food is violently ejected. Diarrhœa is rare, but constipation frequent. The abdomen is retracted in the earliest stages. In the later stages the intestines become distended, and the abdominal muscles yield. The pulse is frequent and small. Respiration runs as high as 40 per minute. Average temperature to 101° to 105° F. The countenance is anxious, like a wild animal in a trap. The mind remains clear throughout the disease. The pallor is a peculiar feature, and death comes with decline of pulse and temperature. The doctor spoke of the great variation in the symptoms of the disease, and remarked that some cases were so masked that they went on to death, and the disease was only diagnosed on the post-mortem table.

The Treatment of the Insane.—Dr. A. B. Richardson advised the establishing of a hospital for the treatment of the curable insane of the country, to be under the care of a special staff, also a consulting staff of physicians and surgeons. He urged the better teaching of students with regard to the treatment of insanity.

Other papers were: "The Surgical Teaching of Epilepsy," by Dr. B. M. Ricketts, of Cincinnati; "Headaches," by Dr. Phillip Zenner, of Cincinnati; "Chloroform," by Dr. H. N. Brown, of Hillsborough; "Sympathetic Ophthalmia," by Dr. S. C. Ayres, of Cincinnati; "Hysterical Paraplegia in a Child," by Dr. S. P. Deahof, of Potsdam; "Cæsarean Section, with Report of Case," by Dr. J. N. Bartholomew, of Trenton; "Cardiac Diseases in Soldiers," by Dr. F. H. Patton, of the National Military Home at Dayton; "Delayed Operations in Ovariotomy," by Dr. Rufus B. Hall, of Cincinnati.

Chloroform and the Hyderabad Commission.—Dr. J. C. Reeve, of Dayton, a national authority on anæsthetics, handled the commission, their sins of omission, as well as commission, without gloves, denying, and apparently proving his denial, of many of the points of their report.

The officers of the Society elected for the ensuing year were as follows: *President*—Dr. Dan Millikin, of Hamilton; *Vice-Presidents*—Drs. S. P. Deahof, of Potsdam, and R. T. Trimble, of New Vienna; *Secretary and Treasurer*—Dr. W. W. Hall, Springfield. The next meeting will be held at Hamilton, April, 1891.

The Society adopted a constitution and by-laws copied largely from those of the Mississippi Valley Medical Association.

Correspondence.

THE KOCH CURE IN ENGLAND.

(From our Special Correspondent in London.)

London, November 17, 1890.

Great interest is being evoked in this country—both in professional and lay circles—by the announcement of Koch's alleged cure for tuberculosis. Several British physicians and surgeons have already proceeded to Berlin to study the process.

A public demonstration will shortly be given in London of the action of the remedy, Professor Koch having supplied a small quantity for the purpose. Meanwhile, in the midst of considerable enthusiasm, there are many who are judiciously reserving their opinion until further particulars are obtainable. It is needless to say that the public mind has been greatly excited, owing to the prominence given to the subject in the lay journals. A curious advertisement appeared a few days since in one of the daily newspapers to the effect that a medical student who was suffering from phthisis, and had a knowledge of German, might hear of something to his advantage on applying to the advertiser.

SHOULD THE KOCH CURE BE A SECRET?

To the Editor of the Medical Record.

Sir: While corresponding with Dr. N. S. Davis in relation to the discovery by Dr. Koch of a substance which he asserts will cure tuberculosis, I received from him the subjoined communication. Believing that the views on this subject of a member of the medical profession who has the attainments and experience of Dr. Davis would be of general interest, I transmit you the letter for the Medical Record. Truly yours,

Ephraim Ingals, M.D.

Chicago, Ill., November 22, 1890.

Ephraim Ingals, M.D.:

Dear Doctor: I thank you for the note you sent me on the 16th inst., expressing sympathy with my views of the manner in which Dr. Koch had claimed to have made or discovered an important remedy for tuberculous diseases, as given in an interview in the *Evening Post* of the 15th inst. The reporter represented me as using some expressions directly disparaging the character of Dr. Koch that I did not use. After saying to the reporter that I could not express any opinion concerning the so-called discovery of Dr. Koch, simply because he had not informed either the profession or the public what his "lymph" was, or how it was made— neither had he or any of his assistants published or reported any number of cases treated with it by which any reliable opinions could be formed—I said that it was greatly to be regretted that so eminent a man should have been induced to publicly put forth a claim to so important a discovery without

fully and frankly stating its nature, composition, and mode of preparation. Failing to do this, and at the same time announcing that the remedy could be obtained only at a given place, and that only three or four of his medical friends or assistants had been authorized to use it, was plainly announcing a secret remedy for the cure of some of the most prevalent and fatal maladies of the human race, and in direct violation of the oldest and most universally sanctioned rule of medical ethics, which declares that it is "derogatory to professional character for a physician to hold a patent for a medicine or to dispense a secret nostrum, whether it be the composition or exclusive property of himself or others. For if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality." I further said to the reporter that the article from Dr. Koch, published simultaneously in the *Philadelphia Medical News* and the daily secular press of this country, would be certainly followed by intense excitement and the most cruel anxiety on the part of the many thousand consumptives and their friends in all countries. The crowds that would flock to Berlin and to any other points where the "lymph" should be advertised, would far exceed the ability of the few doctors favored with a sample of the remedy to treat properly; and the cruel disappointments that would follow would elicit charges of venality and fraud, much to the scandal of scientific medicine. That each day's development of facts transpiring in Berlin, as furnished through the daily press since that interview with the reporter of the *Evening Post*, shows my predictions only too sadly true is now apparent to all, and nothing but a speedy and full publication from Dr. Koch himself of the nature and mode of preparation of his supposed remedy or "lymph" will save him and his co-workers from overwhelming disgrace. Whether the remedy ultimately proves of much or little value in the treatment of disease, the honor of the medical profession and the sacred interests of suffering humanity are wholly inconsistent with the dealing in secret remedies.

You and I know very well that the real value of any remedy in the treatment of such diseases as those called tuberculous or consumptive cannot be determined satisfactorily until it has been used by many members of the profession in the treatment of a large number of cases through a period of twelve months at least.

Respectfully yours,

N. S. DAVIS.

65 RANDOLPH STREET, CHICAGO, ILL.

AGAIN THE QUESTION OF PRIORITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Last week when I read in the MEDICAL RECORD the article by Dr. Forest on the subject "A method of applying plaster jackets without Sayre's suspension," I was struck with the truthfulness of the saying that there is nothing new under the sun. It was my intention to write to Dr. Forest, as I now do to you, but it passed my mind, until to-day, in reading the article in the MEDICAL RECORD, by Dr. Daniel Brown, I am reminded how unsafe it is for one to undertake to assume credit for improving methods in surgery. In relation to this method I wish to say that the device described by Dr. Forest is not new, to my knowledge, except, perhaps, the iron brackets and the grooves in the side-bars. The essentials of this device I remember to have seen published in some journal in 1883. Following the description then given I had a frame made, which was superior to the one now in question, in that it required less cloth and consequently less waste, otherwise it was of the same pattern. This I used upon three occasions in 1884—first, in a case of my own in Elmira, January 14, 1884; second, in a case in consultation at Cazenovia, N. Y., March 19, 1884, and lastly, in consultation, on a case at Smithborough, N. Y., July 10, 1884. Since then it has rested on a shelf in a closet out of my office.

As far back as in the seventies I also used the "spring scales," in addition to the Sayre apparatus, in some experiments as to the amount of extending force employed. Later I used the scales in developing the different amounts of gravity force implied by the different degrees of incline given to the body on this frame which is now under consideration. Lastly, I used the scales in developing the graduated suspension swing that I described in the *Albany Medical Journal* for November, 1885, page 350.

C. L. SQUIRE, M.D.

ELMIRA, N. Y., November 22, 1890.

THE PRIORITY OF POST-GRADUATE INSTRUCTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The recently published letters of Drs. Roosa and Wyeth may recall to several of your readers the fact that about *ten* years ago one or more post-graduate schools were founded in this city. At least a number of meetings were held, plans were proposed, and professorships accepted. After which the faculty would adjourn for rest and refreshment. Who knows but that these schools may yet materialize, rival those already in the field, and lay claim to priority of establishment?

In the question at issue the facts appear to be as follows: For many years past post-graduate medical instruction in this city has been seriously discussed, and several schools established—on paper.

On April 4, 1882, seven members of the faculty of the University of the City of New York resigned for the express purpose of founding a post-graduate medical school. This event excited much comment in both the daily press and medical journals of that date, and, as is well known, was shortly followed by the opening of the present "New York Post-graduate School and Hospital." During the preceding winter professorships had been accepted in a proposed institution, to be called the "New York Polyclinic," but the first public announcement of this school was not made until a short time before it opened, in November, 1882. In the case of an invention or a discovery the claim of priority is usually awarded to the man who makes the first public announcement thereof, and not to the man who claims to have been the first to think about it.

It may be added in conclusion that both the "Post-graduate School" and the "Polyclinic" are doing excellent work, and have added much to the reputation of New York City as the great medical centre of this continent.

Very truly yours,

GEORGE HENRY FOX, M.D.

November 30, 1890.

"IF YOU GO TO COLORADO YOU CAN NEVER RETURN."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the editorial entitled "If You Go to Colorado You Can Never Return," appearing in the RECORD of November 8th, there is a statement of the opinions of "physicians from Boston" which is liable to give a very wrong impression, and I deem it of sufficient importance to call your special attention to it. The statement was to the effect that in the discussion of papers at Denver, at the meeting of the Climatological Association, "physicians from Boston and other places along the seashore believed it safe for many patients to ultimately return to their homes."

In Dr. F. J. Knight's admirable paper upon this subject he gave the results of his rich experience, and cited cases of patients who had returned to the New England coast, and had lived there with apparent impunity, but I feel very sure he would not wish it to be understood that it is a safe experiment for the majority of cases.

In the discussion of the paper I distinctly took the

ground, judging from a comparatively short experience of nine years' practice, that although there were doubtless marked exceptions to the rule, yet the experiment of returning to the climate where the trouble arose was always attended with risk, and quoted the teachings of my father, Dr. Henry I. Bowditch, who has always maintained that it is better for the patient to remain in the place where he has regained his health, and that a return to the New England coast, except for short visits at favorable seasons, is fraught with danger, as shown by numerous examples, with some exceptions.

As Dr. Knight and myself were the only "Boston physicians," I believe, who spoke on this subject, I felt I ought to correct an erroneous impression given by the editorial mentioned.

Respectfully yours,

VINCENT Y. BOWDITCH, M.D.

113 BOYLSTON STREET, BOSTON.
November 10, 1890.

"THE TEMPTATION OF JOHNS HOPKINS."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Just at the time that an article under this heading appeared in the RECORD, a reception was given at the Johns Hopkins Hospital to delegates from the Ladies' Committees who are engaged all through the country in collecting the Women's Education Fund in aid of the proposed school of that hospital. The delegations, which comprised more than a hundred women from all the principal cities of the Eastern States, were headed by Mrs. Harrison, and were composed of women well known in society, literature, in charitable and progressive work of all kinds.

They were met by the trustees, presidents, professors, and physicians of the university and hospital, and by many of the most prominent women of Baltimore. The women met to congratulate each other on the success of the first step of their enterprise, and to become acquainted with the institution. The authorities of the university and hospital met there to welcome them, and explain to them more fully the character of the school they desired to found.

There was a striking contrast between the dignified and large-minded tone of the meeting, and the singularly narrow and ungenerous tone of the article in question. Standing in the middle of the noble buildings of the hospital, with the evidence of almost unbounded expenditure on every side, the insinuation that Johns Hopkins proposed "to sell its privileges for the inefficient sum of $100,000," and that it was being induced to adopt a course derogatory to its dignity "by the persistent nagging" of a few women, seemed ludicrous. But it is something more than ludicrous that a metropolitan journal could take so petty a view of the question, and treat it in so unworthy a style. To disapprove of the course of the university is fair enough, but to insinuate that its authorities were bribed or cajoled into a course so deliberately adopted, is an insult to the university and to the large constituency of women represented at the meeting, which a leading journal should have more self-respect than to permit itself to offer.

It shows an entire misunderstanding of the situation to say that the success of a few colleges for women proves the absence of any necessity for such action on the part of Johns Hopkins. Every physician knows that it is only the few schools that are based upon great endowments that can rise to the level of university instruction, for this implies large investments for a small class of advanced students. It implies a school that is not "popular," which ignores pecuniary results, and exacts a quality which precludes numbers. Such institutions as Johns Hopkins must be few in number, and cannot be duplicated for the benefit of women. Ordinary colleges, whether for men or women, cannot hope to offer such exceptional opportunities for the comparatively limited class of students who can avail themselves of them.

It is just on this highest level that co-education in some form becomes necessary, if women are to attain this higher plane of study. It is certainly no discredit to the university that it recognizes the justice of the requests of women to share in this higher education, nor to that of women that so wide-spread a desire should be manifested on their part to secure it.

As for the sneers in which the writer of the article in question indulges, they are fortunately more effective as a measure of his own good taste and liberality of spirit than of the character or value of the movement which he ridicules.

EMILY BLACKWELL, M.D.

NEW YORK, December, 1890.

[We are always pleased to give a hearing to the other side, and welcome Dr. Blackwell's criticism accordingly. No one is better able to speak for women than she who has herself done so much to advance female education, and there is none whose opinion is entitled to more respect.—ED.]

MR. TAIT AND HIS PATHOLOGY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue of September 20th you do me the honor to make me the subject of a leading article, with the general tenor of which I have no reason to find fault.

I have, however, just reason to remonstrate with you when you make it appear that I wish the surgeon to sink to the level of a mere craftsman, and that I despise and condemn a good training in anatomy, physiology, and pathology. I do nothing of the kind, and there is nothing in the address which was the object of your criticism which would justify such a conclusion. My argument was the converse, and to the effect that, while being well-trained in anatomy, physiology, and pathology, those who attempt to play the part of surgeons should be taught how to use their hands, and at present they are not so taught—and most of them show their deficiency.

You pass from this to some personal abuse to the effect that "Our great trouble with Mr. Tait is that his pathology is so much at fault that he holds it in contempt. We are apt to do so with our weak points." Your weak point is that you know very little about my pathology, and you are strangely ignorant of the literature of your own country, indeed of that of your own city, in fact I may say you don't know the literature published by Wood & Co., of New York, the firm that runs your own journal.

In your issue of August 23, 1890, at page 211, occurs a long quotation beginning "In 1885 Breisky brought to the attention of the profession a condition of the female pudenda which, although not infrequent, seemed so far to have escaped description, etc., etc."

In Wood's Library of Standard Medical Authors, is a volume on "Diseases of Women," by Lawson Tait, published in 1879, in which (pp. 25 and 26) you will find a far more complete account of the disease and its pathology than is given by Breisky.

I could quote many passages from your own columns where terms of the most appreciative praise of my own work in the pathology of the Fallopian tubes, the ovary, the uterus, and the peritoneum occur, sentences which are wholly irreconcilable with the conclusion of your leading article that "Modern surgical science will not wait even for a Tait to catch up." You complain that I am contraversially disposed, and I certainly am, when I get such good reason as you have given.

I am, etc.,

LAWSON TAIT.

[The very courteous and modest note of Mr. Tait convinces us that we have been in error in appreciating the real line of his argument and in properly understanding its drift. Nor was any personal animus intended in pointing out what we believed to be one of his weak points. It is not always necessary in examining evidence

to abuse the witness. We are, however, glad to be set right on our distinguished contributor's pathology by such direct and impartial testimony. Still the field of gynecological pathology is such a large one, that even our talented cousin may not at all times be able to cover it effectually.—Ed.]

AN ANSWER TO DR. BROWN'S CORRECTION.

To the Editor of the Medical Record.

Sir: In your issue of November 22d, Dr. Daniel Brown takes me to task for putting forth as my own, a method for applying plaster of Paris jackets, the credit for which should properly belong to him.

In my article published November 8th, I make this statement: "Permit me to say that Dr. Daniel Brown of this city, first suggested to me the use of a frame with a sheet stretched across. The cross-bar for the child's hands, the use of the frame in a leaning position so as to get good extension, and the practical application of it in spinal diseases should, so far as I know, be credited to myself."

It will be seen at once that my claims are very modest, and that I gave in my article credit to Dr. Brown for all suggestions of his that I used.

As he makes no claim to suggesting the use of the cross-bar, and rejects as absurd the use of the stretcher in a leaning position in order to get extension, and as it is a fact that he never in his life used an apparatus of this kind nor saw one used (at least he had not two weeks ago), wherein have I wronged him in my three humble claims?

The stretcher that Dr. Brown suggested is simply a slight modification of the well-known hammock method of putting on plaster jackets, and is suggested by the latter, the essential details being the same in each, so that, had I committed the enormity the doctor seems to think I did, and given to the public his idea without giving him all the credit he thinks he is entitled to, still the theft would not have been a great one. However, my article proves that I did not take Dr. Brown's suggested suggestion without giving him all the credit he deserves, and therefore I should stand acquitted.

Dr. Brown says: "Under the circumstances the profession will not fail to appreciate the advantages of inventing from a plan, a model, or drawing, appropriated and lying before you, especially if the inventor has a description with the draft. Invention then becomes as easy as the friends of Columbus found it to stand an egg on end after seeing him do it."

When this statement is stripped of its metaphors, verbiage, and inuendoes, it means, if it means anything, that he showed me models, drafts, and descriptions of the apparatus. This he certainly did not do, nor was it necessary. Simply suggesting a stretcher to be used like the well-known "hammock" method would be all sufficient. The models existed only in the doctor's present fertile fancy.

Another point concerns not a possible mistake on the doctor's part, but a wilful and deliberate misstatement. When he implies that I presented the apparatus before the New York Medical Union a year ago without giving him the credit of having suggested it, he repeats a statement that was never true, and one that has been corrected publicly in his presence.

Let me close by giving the doctor a suggestion in return for the one he gave me.

If in the future he should chance to run against a good idea, and if after turning it over in his mind for three or four years he still has not the energy or skill or opportunity to put it in practice and report upon it, he should not feel grieved, but should rejoice rather, when some one else tries it, and, if good, gives it to the profession at large, while they give to him the credit of having suggested it.

W. E. Forest, M.D.

39½ Washington Square.

LIBRARY OF THE NEW YORK HOSPITAL.

Error Corrected.

To the Editor of the Medical Record.

Sir: On the recent inauguration of the new Academy building, an address was delivered by one of the speakers upon the subject of "Our library," which contained the following very erroneous statement: "Thirty-three years ago, when I was admitted a member of this Academy, there was no medical library or medical reading-room in this city." Whence the writer got his information I know not, for so frequently has the history of the library of the New York Hospital been written and published by city compilers and by United States Government officials that it seems that one possessed of the general information of the speaker should have known that the library of the New York Hospital was founded in 1796, and that when he became a member of the Academy it contained six thousand one hundred and eighty volumes, occupied three apartments, two of them on second and third floors of the old hospital, joined by an iron staircase. All this was as far back as 1857. Thus it appears that our city had a medical library of no mean capacity thirty-three years ago which was used by the profession and by students of medicine.

John L. Vandervoort, M.D.,
Librarian.

"ESSENTIAL HYDROPS."

To the Editor of the Medical Record.

Sir: It may not be too late to suggest a cause which may have brought about the dropsical and other symptoms detailed by Dr. Marcell Hartwig, of Buffalo, in the Record of September 27, 1890, as occurring in his practice, in the person of a young woman; to which group of symptoms he applies the name "Essential Hydrops," and considers it as a discovery, an unchristened and unrecognized member of the already too extensive family of human ills. There is one condition, not rare, which may give rise to the pathological picture described by Dr. Hartwig, namely anæmia. Young women of tuberculous stock are prone to become anæmic. If so, they are "pale," menstruation is "irregular and scanty," although during the early development of the anæmia they may have been considered in good health. In pronounced anæmia of young women regional dropsy, or even general anasarca, is a somewhat common symptom. In the case under consideration the rise of temperature may have been caused by the influence of vitiated anæmic blood on the central nervous system, or again, it may have originated when the doctor settled the point of *virgo intacta*. It seems to me that anæmia would explain the pallor, weakness, menstrual troubles, fever, dropsy, and easily excited circulation. Some preparation of iron might have dispensed with the polypharmacy. In conclusion, I would say that all honor is due the describer and conqueror of a hitherto unrecognized disease; but only after mature study and elimination of common causes of a set of symptoms, should an addition be made to a long list of diseases. I venture this communication as the doctor has not excluded anæmia, nor has he even mentioned it; and, as I have, on my books, the record of a case almost exactly similar, which had been diagnosed as chronic parenchymatous nephritis by a well-known Philadelphia physician, but which rapidly recovered on correction of diet and with the use of iron. This young woman is well after four years. Her disease was diagnosed by me as anæmia, which diagnosis was confirmed therapeutically, and by her prompt return to health.

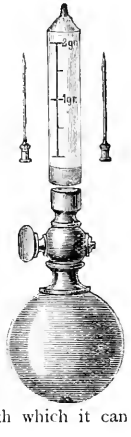
I am, sir, yours faithfully,

V. Haven Ross, M.D.

Buffalo, N. Y., October 13, 1890.

New Instruments.

THE KOCH LYMPH SYRINGE.



We have the pleasure of presenting to our readers an illustration of the Koch Lymph Syringe, which we have just received from Mr. E. Kraus, of Berlin. The instrument is worked by means of a rubber bulb instead of the piston used in ordinary hypodermic syringes. The cylinder, which is glass, has a capacity of two grammes, is accurately graduated, pointed at one end to receive the shoulder of the hypodermic needle, and squared at the other to adapt itself to the bulb attachment. The cylinder, after being filled with the requisite amount of lymph, is then attached to the bulb, the stop-cock of which has been previously shut. After the needle is inserted under the skin the stop-cock is opened and the fluid injected by pressure upon the bulb. The advantages claimed for the instrument are its simplicity, efficiency, and the ease with which it can be kept clean.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 23 to November 29, 1890.

Ewing, Charles B., Captain and Assistant Surgeon. By direction of the Secretary of War, in addition to his present duties, is assigned to duty as examiner of recruits at St. Louis, Mo. S. O. 275, par. 7, Headquarters of the Army, A. G. O., Washington, D. C., November 24, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 29, 1890.

Crawford, M. H., Passed Assistant Surgeon. Ordered to the Receiving ship Independence.

Marsteller, E. H., Passed Assistant Surgeon. Ordered to the Petrel.

Nash, Francis S., Passed Assistant Surgeon. Resigned, to take effect November 23, 1890.

Cordeiro, F. J. B., Passed Assistant Surgeon. Granted extension of leave for four months, with permission to leave the United States.

Lansdale, Philip, Medical Director (Retired). Granted one year's leave, with permission to leave the United States.

Alfred, Adrian Richard. Commissioned an assistant surgeon, from November 24, 1890.

A Point in Etymology.—Blackberries are often called bumble-kites, from bumble, the voice of the bittern, as in Chaucer; and kite or kyte, a Scotch word for belly; the name bumble-kite being applied, says Dr. Prior, from the rumbling and bumbling caused in the bellies of children who eat its fruit too greedily. The blackberry fruit has also acquired the name of scaldberry, from producing, as some say, scaldhead in children who devour the fruit to excess, or, as others declare, from the supposed curative effects of the leaves and berries in that disease of the skin; or, again, it may be from the use of the leaves as applied to scalds.—Dr. W. T. Hernie in *The Hospital* for June, 1890.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 29, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	17	5
Scarlet fever	79	10
Cerebro-spinal meningitis	2	4
Measles	236	12
Diphtheria	86	22
Small-pox	1	0
Varicella	9	0
Pertussis	0	0

A Few "Pointers" for the General Practitioner.

Fracture Dressings.—A very valuable suggestion I received in the Windy City was in regard to the lightest kind of a fracture dressing. Plaster bandages are heavy and disagreeable to apply; the same can be said of starch and the others. Get the stuff called "wiggin," used by the fair sex to stiffen certain portions of their clothing. Make it into the necessary size bandages, and when needed soak in hot water and apply; in a short time you have a light, hard dressing, which can be covered with shellac, cut with a sharp knife, and laced as a corset or shoe.

A Reflector.—We all have to throw a light into some cavity of the body at times, and the stronger the light the better, but the beautifully nickel-plated, double lens concentrators cost more than we, perhaps, can just now afford. So, until our cash account grows, we will take a common police dark lantern, cut the rim from top and bottom, solder a piece of reflector on the posterior wall and set it on any kind of a lamp, and if the chimney won't fit inside put it on top, and you have a good concentrator of rays, and one which you can throw in your bag to carry and use anywhere.

An Insufflator.—After you have turned the light from this down someone's throat they will remember that the baby has an earache, and as you will need something better than the paper cone to blow the necessary boric acid at the diseased part, we will manufacture an insufflator; take a hard-rubber thermometer case and an atomizer bulb, cut the thermometer case in half, drill a hole in the small end, and at the other wind a piece of stiff paper tightly, letting the paper project about an inch beyond the tube; now take the other piece, open up the end and attach the atomizer bulb, cut the other end bias, making a lip with which to scoop up the powder; fit in the paper, squeeze the bulb, and you have quite a respectable powder blower.

Hæmostatic Forceps.—One who is liable to get surgical cases should not be without half a dozen pairs of hæmostatic forceps ready to hand; but if we are not the possessors of these valuable inventions of Tait, we go to a furnishing store and get a card of the ordinary clips one finds on the anterior extremity of our suspenders and on sleeve holders; for ten cents you have a dozen pair of hæmostatic forceps that have held a femoral artery in several cases. They are not built on the antiseptic plan, but boil and soak them in carbolic acid, and the germs will be too ill to cause any trouble.—Dr. H. A. Starkey, *Medical Times and Register.*

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about one hundred and eighty dollars, will be made on July 14, 1891. Essays intended for competition may be upon any subject in medicine, and must be received by the Secretary of the College, Dr. Charles W. Dulles, on or before May 1, 1891.

ACTINOMYCOSIS OF THE LUNG;

BEING THE JOSEPH MATHER SMITH PRIZE ESSAY FOR 1890.

BY EUGENE HODENPYL, M.D.,

FIRST ASSISTANT IN PATHOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

IN 1878 J. Israel showed that actinomycosis, first described in animals by Porroncito, in 1875, also occurred in man; and it was early shown to be due to the presence of actinomycis, or the "ray fungus." Since that time upward of three hundred cases have been reported, and actinomycis has been given a provisional place in our present classification of the bacteria. It has several times been isolated, grown on artificial culture media, successfully inoculated into animals, and, in fact, is now definitely proven to be the cause, and the only cause, of the disease.

The disease is wide-spread, having been observed in almost all parts of the world, although the greater number of the cases have been in certain parts of Germany, Russia, and Austria. But few cases, comparatively, have thus far been recognized in this country. So large a number of cases have been seen during the past two years, it would seem as if the disease were actually on the increase; or, as is more probable, with the more wide-spread knowledge among physicians of the malady, it is more frequently recognized. Actinomycosis, in man, has been observed in almost every organ and every tissue of the body; although, as is also the case in animals, the disease more commonly affects, primarily, the regions about the jaws. Rutimeyer estimates that about fifty per cent. of all cases are of this class, in twenty per cent. the lungs, and in fifteen per cent. the gastro-intestinal tract are the parts first involved.

For the following two cases I am indebted to Drs. F. Delafield, and Charles McBurney.

CASE I.—S. O——, aged eighteen, female, native of Sweden. Admitted into Roosevelt Hospital. For past six months has not felt well. For three weeks previous to admission has suffered from pain over the right side. Dyspnœa, severe cough with profuse fetid expectoration, fever, night-sweats. On admission, patient pale and emaciated; pulse, 104; respiration, 32; temperature, 98° F.

Physical Examination.—Over the right side of the chest, from the spine of the scapula to one inch above the angle, dulness, thence downward, flatness. Over the dull area bronchial voice, breathing, and whisper; over the flat area diminished breathing and distant voice. Vocal fremitus less marked than on the left side. Over the left side exaggerated breathing and distant voice, with a few subcrepitant râles. The dulness over the right side gradually extended to the apex, so that the lung became completely consolidated. Patient complained of constant pain over this side, which was also painful on pressure. The cough, with offensive expectoration (not examined microscopically), continued. The fever was constant but irregular, and was accompanied by attacks of sweating. An area of redness, swelling, and fluctuation formed over the right side, just below the costal border, which was incised, and about one pint of pus evacuated. The patient gradually grew worse, and finally died, exhausted, about five months after the commencement of the disease.

Autopsy, by Dr. Delafield. Left lung very large and œdematous. There is some diffuse hepatization over the upper part of both lobes. Right lung completely adherent to the chest-wall. Bronchi contain pus. Lung completely consolidated, with thickening of the connective tissue, and a very general broncho-pneumonia.

The lung is of fair size; no part of it is gangrenous. There is a small collection of pus shut in behind the posterior aspect of the right lower lobe, just above the diaphragm, and communicating with the abscess in the back. There is a suppurating sinus behind the lung, between the pulmonary and costal pleuræ, running up along the vertebral column; and behind, the ribs and vertebræ are eroded. The lung emitted a peculiar fetid odor, similar to that which had previously been noticed in the sputum. The other organs showed no gross lesions. On account of the fetid odor, and the absence of gangrene, or other distinctive features in the lung, it was suspected that the case was one of actinomycosis.

Microscopical Examination.—By a variety of inflammatory processes the lung has become profoundly altered. The larger bronchi show intense bronchitis. In the medium-sized bronchi, besides inflammation, there is well-marked dilatation of some. In others there is further added a growth, into their lumina, of organized connective tissue containing blood-vessels (see Fig. 1). Although growths of organized connective tissue into the lumina of the air-vesicles are not infrequently seen, similar growths in the bronchi, especially in those of considerable size, have not, so far as I know, been described. The walls of the bronchi are infiltrated with pus-cells, and the surrounding air-vesicles are hepatized, or are the seat of interstitial pneumonia.

The smaller bronchi are very generally converted into little abscesses, and frequently, imbedded in these pus-foci, actinomyces are found, usually surrounded by a zone of necrosed cells. While some stain diffusely and with difficulty, and are of a homogeneous or finely granular character, even sometimes calcified; others show fairly well radiation, and with the Gram method the usual hair-like threads of the bacterium. None of the clusters, when examined in water or glycerine, show the usual club-shaped extremities to the threads.

Scattered about the lung, and making up about one-third its entire bulk, are patches of dense fibrous tissue, in which no trace of the former structure is preserved. In other parts are seen various phases and combinations of simple hepatization, with interstitial and intra alveolar (organized connective tissue) pneumonia. In places the air-vesicles are filled with desquamated epithelium, pus-cells, and fibrin. In other places, either with or without exudation, the walls of the air-vesicles are thickened, and growing into the lumina of some of them are growths of organized connective tissue. Here, as is sometimes observed in these intra alveolar growths, the cells covering them and lining the air-vesicles and air-passages are of a cuboidal shape. That is, they have reverted to their fœtal type. The blood-vessels generally are the seat of arteritis, with thickening of their walls.

CASE II.—J. F——, aged thirteen, school-girl. Patient was perfectly healthy up to three months ago, when she had an attack of broncho-pneumonia from which she never entirely recovered, but has continued to cough until the present time. Six weeks ago she noticed a painful

swelling over the right shoulder-blade, which has gradually increased in size. On admission into Roosevelt Hospital the swelling over the scapula measured six by four inches. It was incised, and a considerable quantity of pus and necrotic tissue was evacuated. The cough, which was accompanied by considerable expectoration, gradually increased in severity. Shortly before death an abscess formed in the right axilla, which was evacuated. Death took place about four months after the commencement of the disease.

Autopsy.—Left lung, a few old adhesions and some fresh fibrin on the pleura. There was broncho-pneumonia of the lower lobe.

Right lung completely adherent to the chest-wall, except over a small part of the lower lobe. Pulmonary pleura over the upper lobe is very much thickened. The bronchi are congested and their walls thickened. There are small zones of peri-bronchitic pneumonia in the upper and lower lobes. The upper lobe is small, and bands of fibrous tissue run into it from the pleura. The bronchial glands are enlarged, but not cheesy. The first, second, and third ribs are eroded.

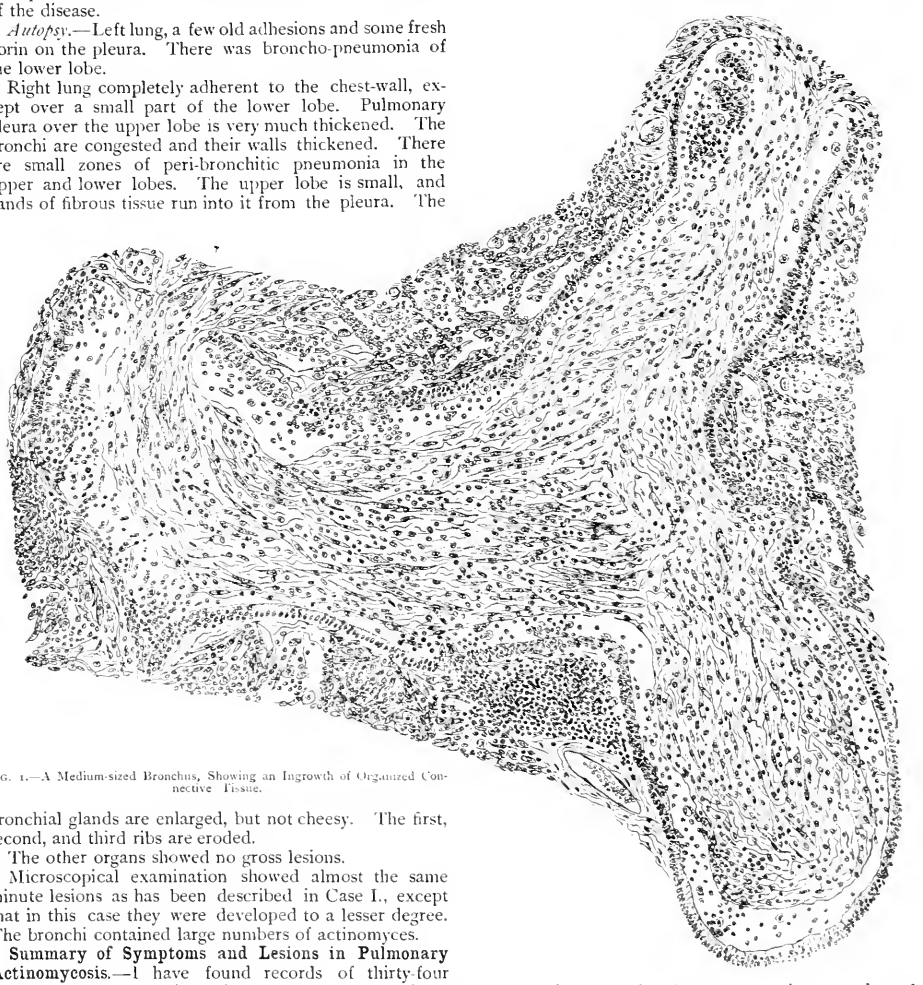

FIG. 1.—A Medium-sized Bronchus, Showing an Ingrowth of Organized Connective Tissue.

The other organs showed no gross lesions.

Microscopical examination showed almost the same minute lesions as has been described in Case I., except that in this case they were developed to a lesser degree. The bronchi contained large numbers of actinomyces.

Summary of Symptoms and Lesions in Pulmonary Actinomycosis.—I have found records of thirty-four cases of the disease, including the two just described. Mossburger, Baumgarten, Eichwald, Ullmann, Mossdorf-Birch Hirschfeld, Koschlakow, Munch, Canali, Petroff, Weigert, König, Conti, Rotter, Paltauf, Wildermuth, Wolff, each a single case; while 5 are by J. Israel; Ponfick, 2; Jakimovitsch, 2; Golubrim, 2; Braun, 3; and Szemasy, 2.

Of these, fourteen include a description of the autopsy. The following summary of the symptoms, lesions, treatment, and certain points in diagnosis, is based upon these cases.

Pulmonary actinomycosis may be defined as a chronic, infectious disease of the lung depending upon the presence of actinomyces. It may further be characterized as being attended with fever, cough with more or less profuse, often fetid, expectoration, pain in the affected side, progressive emaciation, a well-marked tendency to the secondary involvement of adjacent parts, and to the formation of secondary abscesses (actinomycotic) elsewhere. It generally terminates fatally.

As a rule, and perhaps in all cases, the living germ is first taken into the bronchi, and from thence gains access to the parenchyma of the lung.

The ages of the patients varied from nine to sixty-three years; although the majority of the cases were in young adults, and a somewhat larger proportion were in males than in females.

Fever was present in nearly all cases. Usually it was one of the first symptoms, but sometimes it did not come on until later in the course of the disease; it was constant, but of an irregular type, and seemed dependent upon the extent and nature of the lesions, and later by the development of pus-forming centres.

Cough and Expectoration.—Of special importance, and usually the first symptom to be complained of, is cough. It lasts throughout, generally becoming more and more severe. The expectoration varies a good deal, according to the severity of the cough. It was profuse in many cases, often spoken of as fetid, occasionally bloody, and sometimes contained actinomyces.

In Canali's unique case, that of a girl who suffered

for a considerable time from bronchitis, the only symptoms were cough, with profuse fetid expectoration containing actinomyces. The patient, who greatly improved during the summer months, continued without additional symptoms for several years, until she finally passed from observation.

Pain over the affected side was present in all but the above-mentioned case, and was as a rule constant and severe.

Attacks of sweating were mentioned in several cases.

Hæmoptyses were not observed, although the sputum was sometimes tinged with blood.

Shultz, two, Matschiuski, Kirschew, and Eichwald. The remaining nine cases were diagnosticated on finding the bacterium in pus obtained from abscesses which communicated with the lung.

In the cases in which the diagnosis was not made, no mention was made of the sputum being examined; moreover, we are not informed, in the nine cases in which the sputum showed actinomyces, at which period of the disease they first made their appearance. We are, therefore, not in a position at present to determine the earliest time during the course of the disease when we may reasonably expect to find the germ in the sputum of pulmonary ac-

Fig. 2.—A Smaller Disorganized Bronchus Containing a Cluster of Actinomyces.

Emaciation was gradual, and often became extreme; sometimes the patient passed into the so-called "typhoid state;" or, as happened in many, other organs became involved, or extensive abscesses formed beneath the skin which, opening externally, left fistulæ into the lung. As a result of the excessive production of pus, a condition described as chronic pyæmia, and attended with chills, sometimes ensued.

Physical signs were very variable, according to the condition of the lung in the different cases. There were always signs of bronchitis, usually of consolidation, sometimes of cavities, or of empyema.

Duration.—The average duration was ten months; the shortest case lasted four months, and the longest was still living after a duration of several years.

Prognosis.—Of the thirty-four cases all have died except two. Canali's case, already referred to, was lost sight of; and Soltmann's case was pronounced cured (?) after four years.

Diagnosis.—In eighteen cases the disease was positively diagnosticated during life by the detection of actinomyces. In nine cases they were found in the sputum, in the cases of Israel, Canali, Braun, Jakimovitsch, Affanassiew, and

tinomycosis. From the fact that the bacterium has been found in sputum in large numbers, and also that it is commonly found in the bronchi after death, it is to be presumed that actinomyces are likely to be contained in the sputum during life, although in certain instances, possibly, not until the disease is considerably advanced. Inasmuch as actinomyces are the only positive evidence of actinomycosis; and since the disease in the lung may often resemble, clinically, certain forms of pulmonary tuberculosis; and further, since it may be of more frequent occurrence than is at present generally supposed; it is advisable, in the routine examinations of sputa for tubercle bacilli, to further determine the presence of actinomyces.

As found in abscesses, or when seen imbedded in the tissues, actinomyces present such characteristic appearances, microscopically, as are not to be easily mistaken. But sputum may contain certain other bodies so closely resembling the "ray fungus" that careful observation is required in order to distinguish between them. In his original monograph, J. Israel, and later Affanassiew, described masses of leptothrix as closely simulating actinomycees. Bizzozero ("Manual Clinical Microscopy," p. 141,

Paris, 1885) calls attention to certain degenerated epithelial cells; and, more recently, Loesch (Congress of Russian Physicians, St. Petersburg, 1889) to collections of leucin crystals as also liable to be mistaken for actinomyces. Although not generally mentioned in text-books on clinical microscopy, this resemblance of various structures to the "ray fungus" is of important practical value in the examination of sputum. Leptothrix threads may grow about the summits of the papillæ of the mouth, in a radiating manner, and these masses, becoming detached and mixed with the sputa, form the masses, somewhat resembling the bacterium of actinomycosis, and have therefore been called "false actinomyces." They are to be differentiated by the presence of epithelial cells about their centres, the absence of club-shaped extremities to the radiating threads, and by the thicker, coarser rods of leptothrix compared with the delicate hair-like threads of actinomyces.

Fetid expectoration is a common symptom, and is of some diagnostic importance. It was not present in all cases, nor is it confined to this disease; but it is of sufficient importance when present to suggest microscopical examination of the sputum.

Treatment.—Thus far treatment has been purely symptomatic, except in one case where operative measures were resorted to, apparently with the result of prolonging the life of the patient. It is to be remembered, however, in explanation of the present unsatisfactory results of treatment, that in many of the cases the diagnosis was not made during life, or not until late in the course of the disease, and that most of the cases were of hospital patients; consequently the treatment instituted was of necessity under unfavorable circumstances. When we recall the remarkable results being obtained from the climatic treatment of pulmonary tuberculosis, and also the facts that actinomyces withstand the action of even comparatively weak antiseptics with difficulty, and also that they seem prone to die in the tissues, and to undergo absorption or calcification, we may confidently hope that the immediate removal of the patient to a more suitable climate, together with an intelligent application of antiseptics to the bronchial mucous membrane, may give better results than have thus far been obtained. There seems to be no evidence to show that the disease may be transmitted from one person to another, although Affanassiew saw two children of the same family who were both suffering from the disease at the same time.

Pathology.—The lesions are, as a rule, unilateral in about the proportion of 3 to 1, or the lungs may be affected unequally.

They may be classified into three groups.

1. There are the lesions of chronic general bronchitis, the germ being found in the sputum, as illustrated by Canali's case. Such a variety is based solely on clinical grounds, as no opportunity has thus far been had of demonstrating such a condition post mortem.

2. Scattered throughout the lung are large numbers of small dense nodules looking like miliary tubercles to the naked eye. There is no hepatization, and such a lung resembles very closely the gross appearances of acute miliary tuberculosis. On microscopical examination the nodules are composed of clusters of actinomyces surrounded by a zone of granulation-tissue. Munch has seen such a condition in the lung of an ox, no example of this group having been seen in the human cases.

3. Comprises most of the cases of which the author's are examples. The cases vary as to the extent of lung involved. In one it was confined to the apex of the right lung. In the others the whole of the lung was involved. The affected lung was normal, or diminished in size. Pulmonary and costal pleuræ were firmly adherent. There was intense bronchitis of the larger bronchi, and a general broncho-pneumonia, more or less diffuse hepatization, and a well-marked thickening of the connective tissue (interstitial pneumonia). Although not in essential relation to the disease, large numbers of staphylococcus pyogenes aureus and streptococcus pyogenes were found in the lungs, resulting in abscesses, usually of small size, but sometimes sufficiently large to form cavities, which were diagnosticated during life. In certain parts of the body Böstion has shown that actinomyces may develop without the presence of pus. In the lungs the production of pus was an important feature of the cases. Actinomyces were found in the bronchi, broncho-pneumonic nodules, the abscesses, or sometimes in the air-vesicles.

Secondary lesions may develop in almost any part of the body. In all of the autopsies were found secondary lesions. Most frequently pus formed in the pleural cavity, usually sacculated; the ribs, sternum, or vertebræ were eroded, and abscesses beneath the skin adjacent developed; or the pericardium, heart, or opposite lung became involved; or the disease extended to the abdominal organs; or, as in a single case, to the brain. In one case the specific growth penetrated the portal vein, and metastases all over the body were formed; and in another case the vertebræ became so greatly eroded as to cause marked deformity, so that the case was mistaken for one of Pott's disease,

In many cases there was developed amyloid degeneration of the organs.

A Lawyer on Medicine.—M. Barboux, the advocate, in a recent celebrated case in the French courts, thus paid his respects to the medical profession: "When a physician has observed one case he doesn't hesitate to generalize, and when he has met with ten he begins at once to classify them, and as soon as he has done that he makes an assertion of some kind. At the beginning of this century Broussais advised blood-letting, and things went to such a pass that it was said the leech had been enthroned. The pupils of this professor, too faithful followers of his precepts, shed more blood than ever did Napoleon in all his wars. Their successors found that the next generation was anæmic—and small wonder—and then iron was their sheet-anchor. To-day is the day of the microbe. It is found everywhere. If only they might find the microbe of foolish classifications and rash affirmations—then the cycle would be complete!" M. Barboux has evidently not much of an intellect, for he might have hit us much harder had he but had the wit.

TRENDELENBURG'S NEW OPERATING TABLE, DESIGNED FOR OPERATIONS IN THE POSTURE BEARING HIS NAME.[1]

By WILLY MEYER, M.D.,

ATTENDING SURGEON TO THE GERMAN AND NEW YORK SKIN AND CANCER HOSPITALS.

Mr. Chairman and Gentlemen: At the last meeting of the German Surgical Society, April 9 to 12, 1890,[2] and at the last session of the Surgical Section of the Tenth International Medical Congress, August 9, 1890, Professor Trendelenburg, Chief of the Surgical Clinic at the University of Bonn, Germany, presented his new operating table, a specimen of which was brought along by me from abroad, and is now before you for inspection.

The table, made of iron, japanned, was specially constructed and designed for such operations which are performed with advantage in the posture first recommended by Trendelenburg, in the year 1884,[3] viz., for all operations inside of the bladder (supra-pubic cystotomy, especially if done for the extirpation of vesical growths, plasty for vesico-vaginal and uretero-vaginal fistula, as well as utero vesical fistula), and for laparotomies performed for troubles which are located in the small pelvis. Extirpation of large uterine myomata and fibromata, requiring total removal of the diseased organ, resection of the small intestine for fecal fistula, resulting from a strangulated gangrenous inguinal or ventral hernia, etc.,[4] are also rendered much easier with the help of this posture.

Since the method was published, it has been tried by a great many surgeons and gynecologists in nearly every

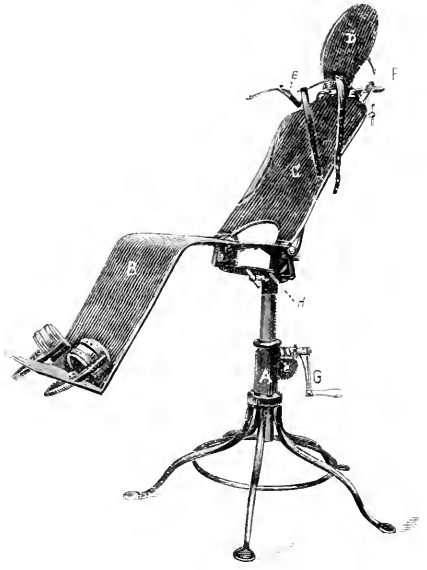

Fig. 1.

country. By far the majority of them were exceedingly satisfied with the same. The only difficulty connected with this posture, which became especially evident in operations occurring in private practice, was to provide a proper and steady support for the patient in the reclined position, without the help of an extra nurse.

Until now I used to fasten a strong kitchen-chair, turned upside down, on a kitchen table, and sawed off the posterior (upper) legs of the chair at the level of the cross bar. The whole inclined plane thus formed by the back of the chair was then covered with folded blankets and a sheet, held in position by a roller-bandage. On this the patient was put, pointing with the head to the window. The legs were either held by a nurse, who

Fig. 2.

turned his back toward the patient,[1] or by a stretcher (Clover's crutch). If the latter was used, the patient's knees rested on the cross-bar of the chair, which, of course, was well padded. In the hospital we used a similar arrangement. But as there always are many hands at our disposal, this slight inconvenience connected with the posture was less perceptible.

Trendelenburg's new table meets this insufficiency of the method in a simple and excellent way, and offers besides many new and important advantages.

It has been constructed by him, in connection with Mr. F. A. Eschbaum, the surgical instrument maker at Bonn, for the special purpose of putting the patient into the required position with great ease, and to bring him back into the horizontal and erect sitting position with a similar simplicity. This enables us to avoid difficulties which may probably arise during a bad narcosis. It may also prove beneficial in other respects.

The table consists of four parts, which can be easily put together, and just as simply taken apart. They are small enough to be sent by an express-wagon to the patient's home. The four parts[2] are: 1. The pedestal

[2] The photographs were kindly taken by Dr. F. E. Sondern, of the house-staff of the German Hospital.

(Fig. 1, *a*); 2. the seat, which has the shape of a coachman's seat on a carriage (Fig. 1, *b*); 3, the rest for the back (Fig. 1, *c*), and 4, that for the head (Fig. 1, *d*). Two movable shoulder-holders (Fig. 1, *e*) are attached to the back-rest.

The back-rest and the seat are connected together by hinges. If everything is in place the table is brought into Trendelenburg's posture by pressing down the handle at the top of the back-rest (Fig. 1, *f*). The table can be lowered to thirty-one inches from the ground, and raised to forty-six inches, by means of a rack and pinion (Fig. 1, *g*), and also swung around a vertical axis (Fig. 1, *h*). If we operate with the help of light which comes from the side, we can always get a full daylight view of the small pelvis and its contents, without moving the whole table. There is a trap-door in the seat of the chair (Fig. 2). If we open it, the whole perineum —urethra (bladder), rectum, or vagina—becomes accessible and can be fully explored, while the patient remains entirely undisturbed in the recumbent position. This proves to be of great advantage in many cases; for instance, if we wish to ascertain the fundus of the bladder with a catheter, which has to be introduced into the bladder during hysterectomy, performed with the help of laparotomy, in closing a vesico-vaginal fistula with the help of epicystotomy,[1] etc.

The patient is put on the table as on an ordinary office chair (Fig. 3). The feet are tied by straps (Fig. 3), and the shoulders caught by the holders mentioned above.

Fig. 3.

Now we can fasten the table with the patient on it "in any height and in any angle of inclination to the horizon, as well as to the meridian, just as we move an astronomical telescope on its foot." If we want to do external urethrotomy for permanent drainage of the bladder, after epicystotomy has been performed in Trendelenburg's posture, and the bladder closed by sutures, the table offers great advantages. We only need to swing the table around in an arc of one hundred and eighty degrees, take the seat out of its hinges, spread the legs with the help of a stretcher, and all is at once ready for the operation on the perineum (Fig. 4). Of course this position holds also good for any other operation on the perineum, vagina, rectum, etc.

I proposed to Mr. Eschbaum to make a number of substitute seats, which are also here before you. If a simple plane be substituted for the curved seat, the table can be well used in the office for ordinary examinations and operations. If we use a narrow seat with divergent

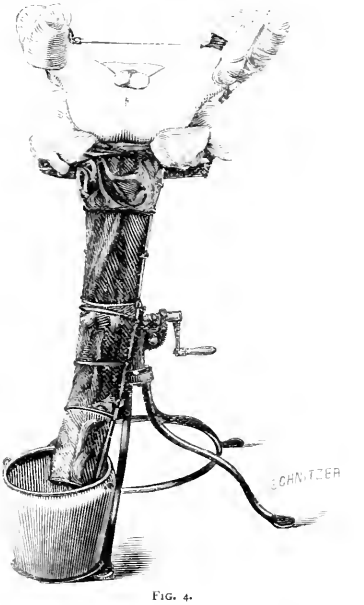

Fig. 4.

foot-holders, which keep the thighs wide apart, urethroscopy can be comfortably performed, and all such operations on skull and face in which the surgeon prefers to let his patient sit up. The operator will have ample room to stand right in front of the patient, between the thighs.

There is no doubt that Trendelenburg's posture has been greatly improved by his new table, and will be still more generally adopted by the use of the same. The table deserves to be found in the operating-room of every public and private hospital.

A FRACTURE OF THE RIM OF THE ACETABULUM;

Complicating a Backward Dislocation of the Hip-joint — Treated by Excision — Report of the Case.[1]

By J. S. PYLE, M.D.,

Canton, O.

In November, 1889, the writer was called to see a case of backward dislocation of the hip joint, complicated by a fracture of the entire posterior portion of the rim of the acetabulum. The rarity of the complication, and the measures adopted for treatment make the case interesting, and one worthy of being placed on record. I am unable at present to find a similar case reported; yet I am of the opinion that where proper means of maintaining reduction have been used, a loss of the rim of the acetabulum is the most frequent, if not the only cause of incurable dislocations of the hip-joint. The reason that surgeons have been silent on this subject, is because they have never adopted radical measures of treatment, and

[1] Read before the Canton Surgical and Pathological Society, Canton, O., August 4, 1890.

consequently the cases were viewed, in real ignorance of their true condition, as instances of imperfect repair of the capsular ligament. The cause of this indifference and ignorance arose no doubt from a lack of faith in what seemed a severe measure with but little possible chance of improvement. I wish to show here that this feminine timidity was unscientific, and above all a hindrance to surgical interference and the progress in the study of the conditions produced in accidental dislocations of the hip-joint. Some rare points will be established in the report of my case; and as a prelude to setting them forth, let me bring a few anatomical facts to bear upon what is to follow. The hip-joint is formed by a reception of the globular head of the femur into a recess in the os innominatum, deepened by circular layers of bone and fibro cartilage until the outside rings almost cover the entire head. The position of this recess, and the direction of the head and neck of the femur, have everything to do with fixing the amount of disability, while in maintaining the articulation, the continuity of the capsular ligament and the rim of the acetabulum are absolutely essential. In regard to the direction of the head and neck of the femur, this varies from the time the shape of that bone is laid down in hyaline cartilage until far in advanced life. At first the head and neck are almost in line with the shaft; but as age advances, they incline, until later on in life, when they form almost a right angle. Every medical man who has had much to do with hip-joint dislocations has observed the different degrees of disability from infancy to old age; and the explanation of this lies in the variation of inclination, as above stated. In a backward dislocation, the way in which the disability is increased may be made still plainer by a few remarks further on the subject. When the head of the femur is thrust backward and out of the acetabulum, the limb rotates inward, describing an arc of a circle, the size of which depends upon the amount of inclination of the head and neck from the direction of the shaft—the immobility of the limb of course being determined by the degree of inclination, and also by the length of that segment of bone. The muscles are not to be disregarded; and here will be a good place to show how they are affected by a change in the position of the femur, and how they operate upon that bone under the circumstances named. We stated that the greater the inclination of the head and neck toward a right angle, the greater would be the arc the femur would describe; and, as a necessary result, the greater would be the disability. Now let us explain; for it is right here where it will require a judicious exercise of the judgment in order to determine how much benefit can be derived from surgical interference in any case of permanent dislocation of the hip-joint. The articulation of the femur with the os innominatum cannot be destroyed without an alteration in the position of the limb. If this be a backward dislocation, the thigh is rotated inward by the internal rotators; and owing to the impossibility of outward rotation on account of the head and neck of the femur lying upon the side of the ilium, the external rotators are put upon the stretch, and the thigh is drawn upward and inward. Now if the arc the femur describes be increased, it is plain that the muscles are made tighter; and adduction and flexion of the thigh upon the abdomen are correspondingly increased thereby, as previously stated, fixing the amount of disability.

Backward dislocations are the only ones attended with a serious impairment of the use of the limb, and for this reason our remarks will be in great part confined to this form.

The anatomy of the acetabulum and capsular ligament are of no less importance to our present study than what has been considered; and we will next give a passing notice to these parts in connection with the injury they sustain in dislocations. The construction of the acetabulum—as described elsewhere in this article—shows that the rings of bone that deepen the cavity were designed, when the articulating surfaces were in contact, to act as a point of purchase for the head of the femur in sustaining the weight of the body in all positions. Destroy this point of purchase, and the result is sure to be dislocation in one of four directions, yet it is no doubt most common that dislocations take place without a loss of the rim of the acetabulum, the capsular ligament being simply torn sufficiently to allow the escape of the head; but I am convinced from the permanent dislocations I have seen that a fracture of the rim of the acetabulum of sufficient magnitude to destroy the function of the joint is not so infrequent as one might suppose. Nothing about the hip joint can be of more interest than the attachment of the capsular ligament. Surrounding as it does the joint, and attached to the neck of the femur and circumference of the rim of the acetabulum, a dislocation cannot take place without tearing the capsule more or less. The nature of this tear is of the most importance to us. A form no doubt more common is a simple separation of the fibres of the ligament; but as verified in my case, another condition of far greater interest to the surgeon than the one just referred to is not, we believe, at all infrequent. This is a separation of a segment of the ligament from the rim of the acetabulum, or, as I believe, always due to a fracture through that part, and the ligament torn away corresponds in extent to the amount of rim loosened up. In these cases the capsule is simply pushed in advance of the head of the femur, and when the dislocation is reduced it is doubtful whether the capsule ever returns to its proper place; and hence the impossibility of complete repair taking place. In the case I base my knowledge on, the comminuted rim with the attached ligament lay at the end of the head of the femur, making it out of the question to restore the fragments and capsule by reducing the dislocation. So I am confident that it may be received as a settled fact that dislocations attended with a torn capsule—as detailed above—cannot completely recover; and if it be a backward dislocation after middle life, excision of the head and neck of the femur will afford the only relief. In regard to operative interference, the degree of disability should be our guide.

The operation of excision promises a useful limb, free from pain, and one, in the exercise of the various movements, not far removed from the normal. I would especially commend it after middle life. My case referred to was a male, fifty-five years of age, and a coal miner by occupation. His injuries were received while at work in a mine by a falling piece of slate striking the unfortunate man upon the back part of the pelvis while in the knee-chest position, thus forcing the head of the femur backward and out of the cotyloid cavity, carrying in advance of it the whole of the posterior portion of the rim of the acetabulum and the corresponding attached capsular ligament. The rim was badly comminuted, and the separation from the innominate bone took place near the bottom of the cotyloid cavity, leaving no purchase whatever for the head of the femur. I saw the patient six weeks after the injury was received; and upon examination recognized the possible condition, giving as my advice directions that an opening be made into the joint, and if found impossible to bring about repair, excise the head and neck of the femur for the purpose of restoring the position and partial usefulness of the limb. This I did two weeks after my first examination. Finding the extent of the fracture beyond my expectations, and seeing that it was out of the question to do anything other than excise, I completed the operation, and the result was in every way gratifying. My patient before the operation used two crutches; but now goes about with a cane, with as much dexterity as if he had a natural hip joint.

This result shows us what may be done for patients afflicted in this way. And now in conclusion let me express due appreciation for a letter of encouragement received from Dr. Lewis A. Sayre while I was pressing upon the patient the importance of the operation.

THE EFFECT OF THE PRODUCTS OF HIGH EXPLOSIVES, DYNAMITE AND NITRO-GLYCERINE, ON THE HUMAN SYSTEM.

By THOMAS DARLINGTON, M.D.,

SURGEON TO COPPER QUEEN CONSOLIDATED MINING COMPANY AND ARIZONA SOUTHEASTERN R.R. CO. HOSPITAL.

In the construction of any work of magnitude, in the present day, involving the removal of rock, dynamite or nitro-glycerine is used in considerable quantities.

When these are used in open cut-work, as on railroads, after the explosion the gases immediately distribute themselves in the atmospheric air, and no effect has been noticed on the workmen employed.

But where it is used in tunnels, as in mining or other partially closed cavities, and the gases or residue are slow to escape from the mouths of the tunnel, or up an air-shaft, serious deleterious effects are produced.

Dynamite is composed of nitro-glycerine with some absorbent. There are, for purposes of study, practically two classes of dynamite, which might be termed inorganic and organic, according to the absorbent used. As a type of one class is that made with infusorial earth—Kieselgour—which is composed of siliceous diatoms, and of the other, that made with ground wood-pulp, or sawdust. Others, still, are made from a combination of both kinds. The results of the explosion, however, are practically the same in either case, except with the organic absorbent we get with the products an additional amount of carbon.

An experience of over five years where such explosives have been in use, and as yet not having read any article on this subject, have led me to believe that one might be of interest to some of the profession.

During 1885 to 1887, while surgeon to the New Croton Aqueduct, fully thirteen hundred cases of asphyxia, or partial asphyxia, and poisoning, from the products produced by the explosion of dynamite, came under my care; and more recently a few other cases which I have had a better opportunity to study.

Two classes of cases were observed: First, where a considerable quantity of the products was inhaled at one time—acute cases; secondly, where the men constantly breathed a small amount, or chronic cases. The acute cases varied according to the amount inhaled.

In some cases where the amount of dynamite used is not large, or where after the explosion a considerable quantity of fresh air has been mixed with the products of combustion, or where the workman has, after a few breaths, become giddy, and is pulled away by others and sent to the surface, the effects produced are a trembling sensation, flushing of the face, succeeded sometimes by pallor, frequently nausea, sometimes vomiting, with throbbing through the temples and fulness in the head, as if it would burst, followed by an intense headache characteristic of poisoning by nitrites—similar to that of nitrite of amyl—only not so violent, but more persistent, frequently lasting forty-eight hours. The heart's action is increased, and the pulse full and round, though somewhat compressible.

CASE I.—J. C——, occupation, miner, while returning to work after a blast, became dizzy, and crawled on hands and knees back to the bucket; felt as if drunk. About twenty minutes afterward was nauseated and vomited slightly. Had a feeling as if his head was swelled. After vomiting the headache increased. The pulse at this time was full and bounding, and 108. Ten hours afterward the headache was more pronounced, and the pulse 88 and more compressible.

Where, however, a man goes into the tunnel immediately after the explosion, and is brought in contact with a large percentage of the poisonous materials, the effects are giddiness immediately followed by unconsciousness, and the patient presents the usual appearance of asphyxia. Sometimes in these cases the pulse is full and bounding, though very compressible; but in most of the cases it is alarmingly weak. Generally there is great pallor, though this may be partially due to working underground. The comatose condition soon passes away, and is succeeded by drowsiness, languor, cold perspiration, intermittent pulse, and generally nausea and vomiting. Sometimes the breathing is spasmodic, and frequently there is hiccough, and after a time a severe headache.

Nearly all of these cases, however, no matter how serious they seem at the time, recover; though a substitute on the Aqueduct, during my absence, was on one occasion so unfortunate as to lose two cases. I found upon inquiry that death in these cases occurred several hours after the patients were removed from the tunnel, and was due to paralysis of respiration.

In the chronic cases there are four prominent symptoms: Headache, cough, indigestion, and disturbances of the nervous system.

The cough is similar in character to the cough of pertussis or of malaria, and at first I was under the impression that it was purely malarial, as cases of intermittent fever were frequent. But although some of the cases may have been complicated with malaria, there were many others that were not, in which the cough was persistent.

In nearly all of the cases there was a continuing headache.

Next in prominence to these symptoms come disturbances of the nervous system, as trembling, irritability, neuralgia, etc. In fact, nearly if not all of the symptoms were attributable to this cause. Even the cough, in all probability, was due to the effect produced on the pneumogastric nerve.

One of the superintendents became so nervous and irritable, largely from this cause, that it was with difficulty that he could get along with the men. All of the men affected seemed extremely nervous. And with this was associated indigestion, probably due to the same cause. Of course, with this latter symptom, the character of the food and the manner in which it was eaten must be taken into consideration. But as soon as a man with these chronic symptoms was taken from the tunnel and placed at work on top, he steadily improved, and would finally recover entirely.

It was also noticeable that those who had previously suffered from dyspepsia or neuralgia were made much worse by the dynamite smoke.

One inspector on the Aqueduct was forced to resign by reason of the constant return of an old "tic douloureux," due to this cause. What were the symptoms recognized due to?

The formula for nitro-glycerine is $C_3H_5(NO_3)3$. And the products from the combustion of this are written: $4(C_3H_5N_3O_9) = 10(H_2O) + 12(CO_2) + 6(N_2O_5)$.

In other words, the products are water, carbonic acid gas, and nitrogen dioxide; none of which would produce the symptoms above described except asphyxia, but not the effect on the heart, nor the other symptoms witnessed. What, then, was the cause?

A comparison of the above symptoms in the acute cases with the phenomena produced by various-sized doses of nitro-glycerine shows them to be identical. This similarity of symptoms from inhalation of the products of the explosion of dynamite, and of those produced by the nitro-glycerine itself, is so well marked that even miners themselves have noticed it. Frequently, when dynamite is frozen a miner will place a cartridge in his boot to thaw it out; and the absorption of nitro-glycerine through the skin will produce precisely the same symptoms as in the mild acute cases of the inhalation of the products before described.

Again, I know an instance of where a miner used his knife to cut a cartridge, and afterward cut and ate an apple with the same knife. In this case, according to his statement, the symptoms were similar to being "knocked out by powder smoke," only more severe. The headache persisted three weeks. And on another occasion this same miner cut up some tobacco to smoke with a knife that he had used for dynamite, and was again similarly affected.

Here the heat from the tobacco inhaled smoke volatilized the fine particles of nitro-glycerine on the tobacco below, and poisoning was produced by absorption through the lung tissue.

No other conclusion can well be reached than the fact that there is mixed with the gases produced unexploded particles of nitro-glycerine in a volatile state; and these particles inhaled by the miners produced the effect described.

There is no doubt but that the explosion of a large quantity of dynamite would produce sufficient gases of CO_2 and N_2O_2 to produce asphyxia. Here we get the cyanosis and other symptoms of simple asphyxia, and we may get nausea and vomiting; but not the same disturbance of the sympathetic system, nor the continued chronic spasms of the vagus, nor the persistent headache pathognomonic of nitro-glycerine poisoning. This fact can be conclusively proved by waving in the fumes, immediately after an explosion, a cold sheet of glass, and thus collecting upon it by condensation a small percentage of the nitro-glycerine itself.

As regards treatment—as a preventative the use of such apparatus or machinery, whether by blowing or by sucking, that will rapidly clear the tunnel or cavity from noxious gases or fumes is to be recommended. Where steam-drills that are worked with an air compressor are used, they contribute largely to this end.

Also, it has been found by makers of dynamite that the use of a large cap will explode a greater percentage of the glonoine than a small one, and this, to a certain extent, obviates the trouble. In certain cases, however, for some reason, a cartridge does not explode, but burns like a candle, with considerable spluttering. In such an instance the amount of nitro-glycerine volatilized is much greater than if exploded, and consequently the effects far more deleterious. I have witnessed a whole "shift" "knocked out" from this cause.

Of course, such measures as are generally used in cases of asphyxia are of service. But in addition to these, the use of cold to the head, and of atropine, ergotine, or other vaso-motor stimulants, administered subcutaneously, are of necessity indicated and exceedingly efficacious. There is little doubt that the effects of nitro glycerine are produced from its decomposition and the formation of a nitrite in the body. "Treatment with ammonia restores normal color and normal functional power to nitrite-poisoned blood."

Acting on this principle, and from its stimulant properties, I have uniformly treated my cases with inhalation of ammonia, and also given the carbonate and aromatic spirits of ammonia internally; and up to the present time have not lost a case.

It seems to me it would be well for those in charge of such works to recommend to the workmen to carry with them small vials of this remedy for use in similar cases.

In none of the cases did I notice any changes in the blood—that is, darkening- such as are mentioned in nitro-glycerine poisoning, but this may have been due to lack of proper observation on my part. In numerous cases of pneumonia the sputum was darker than usual, but this I attributed to the dust and lamp-smoke inhaled.

Harmony and Discord.—A local item culled from the *Medical Standard* runs as follows: Drs. S. J. Wimmer and C. H. May, of New York City, have organized a physicians' musical club.—Drs. Goldenkrantz and Fishman are suing each other for slander.

THE VALUE OF FUCHSINE IN THE TREATMENT OF CHRONIC ULCERS.

By JULIUS ROSENBERG, M.D.,
HOUSE PHYSICIAN, ALMSHOUSE, BLACKWELL'S ISLAND, N. Y.

I HAVE, during the last three weeks, made some experiments with fuchsine, which have been of sufficient success to warrant their being brought to the notice of the profession. It occurred to me at that time that, owing to its great staining and diffusive properties, fuchsine might prevent the growth of pyogenic bacilli, and I then selected several cases of chronic ulcers to be treated with fuchsine. These ulcers were, without exception, in a very unhealthy condition; some were painful, all had much discharge and were bad-smelling. The solutions I employed were:

I.

℞. Fuchsine..... gr. xij.
Alcohol..... O.j.
M.

II.

℞. Fuchsine..... gr. xij.
Alcohol..... ʒj.
Aquæ..... ʒiv.
M.

III.

℞. Fuchsine..... gr. xij.
Alcohol,
Aquæ.....āā ʒ viij.
M.

Of these solutions No. III. has been the most useful. The mode of application is as follows: The wound, after being washed with warm water, is well saturated with the solution, and a piece of lint soaked in the same solution is placed upon the raw surface, ordinary cotton-wool is wrapped around the limb, and bandages applied. This dressing is to be changed every two to four days. The results are very striking; discharge and odor cease immediately; pain, if it has been present, disappears, and healthy granulations soon spring up. Cases which did not respond to other treatment rapidly improved and were cured with fuchsine. I did not observe any bad effects in about forty cases thus treated.

The disadvantages are that it stains so freely, but if a little care is used there is no need to soil the hands or linen. I have found a small glass syringe very useful in applying it, and cotton-wool, which has not been deprived of its oil, will prevent it from penetrating the dressing.

The advantages are: 1. That it is a very inexpensive drug and well adapted for hospital and dispensary practice. 2. It has great analgesic powers, it having arrested pain in every instance. 3. If properly applied it will arrest suppuration and odor absolutely. 4. It produces improvement and cure in most every case.

I will, finally, express my sincere thanks to Drs. E. D. Fisher and C. E. Bruce for their kind encouragement and advice, and report a few cases for illustration:

CASE I.—A. W——, ulcer of right leg, about three inches in diameter, and of twelve years' standing. When first observed was discharging and ill-smelling. Has been treated with fuchsine for two weeks; discharge has ceased, healthy granulations are present and the ulcer is much diminished in size.

CASE II.—James M——, ulcer of left leg, two inches in diameter, of eighteen months' duration, very foul smelling; has been under treatment for three weeks, and is cured.

CASE III.—John M——, ulcer of left leg, two inches in diameter, existed for nine years and presented no intentions of healing; under fuchsine treatment for three weeks, and to-day only a small granulating wound remains.

CASE IV.—Daniel S—— . When brought to the hospital had a number (about ten) of small ulcers on the right leg; duration, four months. Patient had been drinking hard and was in poor physical condition; ulcers have been dressed with fuchsine for three weeks, and patient has been discharged cured.

CASE V.—William D——, has a very large ulcer of left leg, existed ten years, encircles the leg from ankle to middle of calf; has been under treatment for two years without much improvement; ulcer healed rapidly under fuchsine.

RECENT MEDICO-LEGAL CASES.

BY HENRY A. RILEY, ESQ.,
[NEW YORK.

THE President of the American Bar Association gives each year a summary of legislation during the previous twelve months in Congress and the various State legislatures, and this summary contains much of general interest. He made, at the last meeting, the following reference to the legislation designed to preserve the natural food-supply: "The extent and value of the natural food-supply in the form of fish and game, and the importance of preventing its wasteful diminution, perhaps also the growing appreciation of outdoor sports, are illustrated by numerous statutes, in almost all the States, for the protection and preservation of the denizens of the sea, the lake, the stream, and the forest by the establishment of close seasons, by penalties imposed upon the capture of fish by nets, seines, and explosives, and upon the wanton destruction of wild game, the appointment of fish and game commissioners and wardens, by appropriations made for stocking exhausted waters with trout, salmon, shad, and other food-fishes, and by regulating the catch of oysters, clams, and lobsters on the seacoast.

"Stringent provisions are also made in North Dakota and Wyoming for the protection of cattle, horses, and sheep against contagious and infectious diseases, the former appointing a State veterinary surgeon, the latter a board of live stock commissioners, with extensive powers of inspection, quarantine, and still more heroic remedies, in addition to detailed strict requirements concerning the branding and herding of the vast herds of cattle which have replaced the millions of buffalo wantonly slaughtered and now practically extinct. A statute in Wyoming, making it a misdemeanor to pursue, hunt, or kill any bison or buffalo for ten years from March 15, 1890, reads like an epitaph. These measures for the protection of useful animals are supplemented in several States by war waged against noxious ones. A contract between older and newer civilizations is suggested by the bounties which Massachusetts, Ohio, and Michigan offer for the destruction of English sparrows, and the appropriation by Massachusetts of $50,000 for a special commission charged with the extermination of the *Ocneria dispar*, vulgarly called the gypsy moth, as compared with the bounties offered by North Dakota for wolf scalps, with the ears attached, and by Wyoming for the destruction of wolves, bears, and mountain lions, the latter requiring from the claimant not only *prima facie* proof by affidavit, but the entire skin of the animal with all the paws attached, probably as a guaranty of entire good faith." The president made no mention of commissioners whose labors are likely to result in legislation, but the work of the Adirondack commission in this State may well be mentioned here, as there is hardly any non-political measure which is of such universal interest as the endeavor to protect the natural beauties of the North Woods, as well as water-supply which finds its sources in that section. The commission has been holding frequent meetings during the past few months, and suggestions and advice have been invited from all quarters. The lumbering interests, which seem antagonistic to the preservation of the forests in their present condition, have been represented and have given their views. The aristocratic owners of large private parks, who desire to preserve extensive tracts for the exclusive use of themselves and friends, were on hand in good numbers, as well as those whose desire it was to keep unharmed for the use of the public the unrivalled stretches of virgin forest now threatened with destruction.

It is noticeable that no person or interest spoke slightingly of the desirability of preserving the forests, the lumbermen even claiming that their operations really did no harm but added to the beauty of the landscape, by thinning out the too luxuriant growths and permitting the trees which were left to expand with more freedom.

It is certain that the commission will make an interesting report to the Legislature this winter, and will probably present a bill for consideration and action. Some comprehensive measures ought to be adopted at once, or else it is likely that harm may be done which many years of watchful care will not be able to remedy.

The Supreme Court of California has recently decided that the Legislature may probably enact a law requiring that the scholars, as a body, shall be subjected to vaccination. The opinion of the court is partly as follows: "It is suggested that the subject of the Vaccination Act is not within the scope of a police regulation. The Legislature has power to enact such laws as it may deem necessary, not repugnant to the Constitution, to secure and maintain the health and prosperity of the State, by subjecting both persons and property to such reasonable restraints and burdens as will effectuate such objects. The act referred to is designed to prevent the dissemination of what, notwithstanding all that medical science has done to reduce its severity, still remains a highly contagious and much dreaded disease.

"While vaccination may not be the best and safest preventive possible, experience and observation, the test of the value of such discoveries, dating from the year 1796, when Jenner disclosed it to the world, has proved it to be the best method known to medical science to lessen the liability to infection with the disease. This being so, it seems highly proper that the spread of small-pox through the public schools should be prevented or lessened by vaccination, thus affording protection both to the scholars and the community. Vaccination, then, being the most effective method known of preventing the spread of the disease referred to, it was for the Legislature to determine whether the scholars of the public schools should be subjected to it, and we think it was justified in deeming it a necessary and salutary burden to impose on that general class."

In a recent case in Georgia, where damages for a miscarriage were demanded, and where a new trial was granted, the appellate court held as follows: "The tenth ground complains that the court charged that any pain and suffering, or sorrow, resulting from the miscarriage, the law says, is an element of damage. We would suggest that the word 'sorrow' be omitted from the charge of the court on the next trial. It is most too remote to be considered an element of damage, unless it is that sorrow which accompanies the actual injury, and is suffered at the time of the miscarriage.

"The loss of a child by a miscarriage would affect women so differently that it would be hard for men, sitting as jurors, to estimate it as an element of damage; and we think it would be better to omit in the future any instruction to the jury upon the question of sorrow as an element of damage.

"Pain and suffering give a wide latitude to juries, and there are very few complaints made of the smallness of the amounts found by juries upon these two elements of damage."

At the moment when this paragraph is written the fate of the negro murderer, Wood, sentenced to be executed by electricity, is somewhat in doubt, as Judge Brown, of the United States Circuit Court, has granted an appeal from the judgment, while not in set terms giving a stay of the execution. It is not believed, however, that Warden Brush, of Sing Sing Prison, will hesitate to postpone the execution, even if Judge Brown does not come to his aid by explaining the meaning of his order.

The most serious view of the matter for the public, however, arises from the fact that the act of Judge Brown makes the third interference within a year, by Federal

courts, in murder cases decided by the New York State courts. If these appeals to the National courts are to be permitted on purely technical points, it will be difficult to secure the actual execution of a murderer until years have passed after the commission of the crime, and the recollections of it has largely passed away. The quick following of punishment upon crime in English murder cases is certainly to be preferred to the long delays permitted under our procedure.

Clinical Department.

POISONING BY SULPHONAL.

By F. H. DILLINGHAM, M.D.,

NEW YORK.

THERE has been so much said about the safety of sulphonal, and its having no effect on the heart, that I have thought it best to report a case where an elderly lady took ninety grains by mistake and alarming symptoms followed.

I had ordered for insomnia some powders, each containing thirty grains of sulphonal, with directions to take *one* in the evening.

I was called in great haste about 3 A.M., and found her in a semi comatose condition, rapidly passing into a state of stupor, with stertorous breathing. Her radial pulse was almost imperceptible, and extremities cold.

I was told that she got out of bed to urinate a short time before, and was unable to get back, and fainted.

As soon as I had prescribed for the alarming symptoms I made an investigation, and found that she had taken *three* powders (ninety grains) at 9 P.M.

Her breathing and stupor soon improved, and her pulse became a little slower and stronger. Inco-ordination of all the muscles was extremely well marked. Her face was drawn slightly to the right side, and there was ptosis of the right eyelid. Pupils were normal.

She would doze for a few minutes and then open her eyes, but not recognize anyone.

Dr. Charles W. Packard kindly saw the case with me at 6 A.M., when her general condition had slightly improved. As the doctor came into the room, she tried to ask who he was; before this, she had not seemed to appreciate the fact that anything had happened.

Her articulation was very poor and feeble, and it was with the greatest difficulty that I could understand what she wished to say. Respirations were 24, pulse 130, and temperature 98° F. Her mouth was parched and tongue dry, and when she put it out, it deviated to the right. She had a constant desire to urinate, but passed only about a teaspoonful at a time. The urine was normal.

When she attempted to raise her hands, she found it impossible to touch the place she desired.

At noon there was a slight improvement in her condition, but the inco-ordination remained about the same. She had not slept, and it was difficult to obtain an answer to any question; if you did, it was apt to be incoherent.

As her bladder was beginning to be distended, I had her urine drawn by catheter. She complained that she felt so tired, and wished that she could get a little sleep.

The next morning she was much weaker, in spite of the stimulants and milk she had taken, and her mind was not clear. Respirations were 22, pulse 130 and feeble, temperature 98½° F. Her face was not drawn quite so much to the right, and the inco-ordination and ptosis very slightly improved. Her bowels were constipated, but there was considerable tenesmus, which was finally relieved by enemata. She was not able to expel the fæces in the lower rectum, and there was also paralysis of the sphincter muscle, as she could not retain the enema. The paralysis of the bladder still continued.

In the afternoon her mind became clear, but it was with difficulty that she could articulate; she said it tired her so much. The inco ordination was still well marked, and it was impossible for her to use her hands for anything. She tried to write her name, but failed.

After this her condition gradually improved, and when she was able to raise her head, complained of dizziness.

It was ten days before the ptosis, paralysis of the face, and inco-ordination of the muscles entirely disappeared. The paralysis of the bladder and bowels continued for two weeks, and then they began to gradually resume their normal functions.

This case especially differs from the others reported, in the depressing effects on the heart and the absence of sleep, also in the severity and persistence of the symptoms. It does not seem as though a drug which had proved fatal in dogs, and may cause such alarming symptoms, can be absolutely safe, even in smaller doses.

344 LEXINGTON AVENUE.

RELATION OF SLEEP TO TEMPERATURE.

By A. D. BARR, M.D.,

CALAMINE, ARK.

IN an article entitled "The Physiology of Sleep," published in the Kansas City *Medical Record*, March, 1890, the writer called attention to a falling of the temperature before sleep begins, or coincident with it. The writer's observations have now extended over a period of a year and a half, and confirm all claims made in the paper above referred to. Previous observers have held that the body temperature rises rapidly from 6 A.M. to 10 or 11 A.M., and then more slowly to 6 P.M., when it begins to decline, reaching the minimum between 4 A.M. and 6 A.M. The writer's observations, however, tend to show that the temperature rises steadily from 6 A.M. till about noon, when it reaches its maximum. Here it remains, under ordinary circumstances, until 5 or 6 P.M., when it begins to decline, and continues to do so until 3 or 4 A.M., when it reaches its minimum.

The relation of sleep to temperature is shown by the subnormal temperature, 97° F., after the loss of a night's sleep; which, however, will rise to the normal on mental or physical exercise, to fall immediately when quiet is restored.

Progress of Medical Science.

How the Pathogenic Bacteria do their Harm.—Brieger and Fränkel have studied this question. Of course, the first condition for successful inquiry was to employ pure cultivations of the organism experimented upon. Basic bodies, denominated "toxine," had already been found in several pathogenic micro-organisms, such as the bacillus of typhoid, tetanus, cholera, etc. Yet it was found that this toxine did not invariably call forth all the phenomena of the infectious diseases due to the bacilli, from pure cultivations of which it had been obtained; the supposition, therefore, seemed fair that, besides the already-found chemical bodies, there were other substances which played a momentous part (*The Edinburgh Medical Journal*). Brieger and Fränkel considered that Löffler's bacillus of diphtheria was well adapted for their purpose, because it is now beyond doubt that this organism is the genuine cause of diphtheria. Löffler had already called attention to the fact that this bacillus, when inoculated on animals—guinea pigs and pigeons—colonized only the immediate neighborhood of the infected spot, yet grave alterations of texture and organs and speedy death of the animals experimented on followed. This connection of events could only be explained in this way—that the bacilli produced by their local multiplication a substance of exceedingly poisonous properties, which spread over the whole organism, and, independently of the bacteria, did its deadly work. Brieger and Fränkel consider that they have proved that Löffler's diphtheria bacillus

engenders in its pure cultivation a poisonous, soluble substance separable from the bacteria, and which, when injected into susceptible animals, calls forth the same phenomena as the injection of the living micro-organism. The authors also have settled that this substance is destroyed by a heat of 140° F.; that it can stand a heat of 122° F., even in presence of excess of muriatic acid. This last fact of itself speaks against the supposition that the poison of the diphtheria bacillus is a ferment or an enzym. Further examination of this substance showed it was not a ptomaïne or toxine; no crystallizable substance, save kreatinin and cholin, was obtained. Shortly summing up their investigations, the authors seem to have discovered in the diphtheria bacillus a substance belonging to the albumin series of bodies, which has poisonous properties, and causes the phenomena of diphtheria when injected. They propose to give it the name of "toxalbumine." In the living body they consider that the bacteria build up and separate their toxalbumine from the albumin of the tissues. Brieger and Fränkel also examined typhoid, tetanus, and cholera bacteria, and staphylococcus aureus and watery extracts of the internal organs of animals killed by anthrax, in the same way as they had examined the diphtheria bacillus, and found in all of them bodies which, according to their chemical behavior, were albuminoids, were poisonous, and could therefore be aptly called toxalbumines. The road from normal constituents of the body to substances of the most dangerous kind seems a very short one, and our organism itself may be looked upon as the proximate cause of morbid conditions let loose by the life-activity of bacteria.

Administration of Iodine and Phosphates to Infants.—Dr. Jolly considers that phosphates of potash, soda, and iron are absorbed directly, but that the phosphate of lime only enters the system in combination with albumin in small quantities. The greater portion of the phosphate of lime is assimilated by the intercellular formations. Cows fed upon forage and grain give milk containing a large proportion of phosphates. A cow which yields fifteen litres of milk will drink about fifty litres of water, and, from this water, obtains the lime necessary for the assimilation or transformation of all alkaline phosphates of its food. Instead of giving phosphate of lime to infants, he feeds them on aliments rich in alkaline phosphates—*e.g.*, bran bread, and administers alkaline mineral waters, which favor the intracellular formation of phosphates of lime. Chloride of sodium transforms the phosphate of potassium that is contained in vegetables into phosphate of soda.—*Journal de Médecine de Paris.*

The Prophylaxis of Diphtheria.—A *résumé* of this subject is furnished by Professor Löffler, of Greifswalde. The cause of diphtheria is a bacillus, which, contained in the exudation on the affected mucous membranes, is liable to be disseminated in the vicinity of the patient, together with particles of the false membrane. The infectivity of the patient may even persist for some days after all traces of diphtheritic exudation have disappeared. The strictest isolation of cases is necessary; children who have suffered from the disease should be kept from school for at least four weeks. The bacilli have been found to retain their vitality in dry membranes for from four to five months. It is therefore essential that all clothing, bed linen, and utensils likely to have been contaminated should be disinfected, either by boiling or by exposure to steam. The room occupied by the patient should be disinfected by washing the floors with warm sublimate solution (1 in 1,000), and cleansing the walls and furniture with bread.

It is uncertain how long the bacilli may exist in the moist state, but it seems probable that moisture is more favorable to their vitality than dryness. Thus, diphtheria would seem to be favored by the dampness of dwellings, and also by absence of light. These organisms can exist outside the body at a temperature of 68° F., and they develop well in milk. The sale of milk should therefore be carefully supervised. The diseases affecting pigeons, fowls, calves, and pigs, which resemble diphtheria, are not caused by the bacillus of human diphtheria. These diseases in the lower animals are not, therefore, to be feared as sources of the human affection. Professor Löffler thinks that the etiological identity shown by Klein to exist between diphtheria in cats and in man requires confirmation. Although lesions of mucous membranes favor the retention of the virus, yet in disposed subjects the disease may arise apart from such lesions. It is advised that when diphtheria is prevalent, a systematic use of disinfectant gargles and washes (*e.g.*, sublimate solution, 1 in 10,000) should be enforced on all children. The meteorological conditions which favor the spread of the disease are still unknown.—*Berliner Klinische Wochenschrift.*

The Subcutaneous Use of Mercury.—According to the *Hospital Gazette*, a new mercurial for hypodermic use is the so-called glutine-peptone sublimate. It seems that these compounds of mercury with complex organic bodies are coming into favor for subcutaneous use. Glutine-peptone sublimate is prepared as follows: Gelatine is acted upon by dilute hydrochloric acid and a substance called hydrochlorate of glutine-peptone is produced, containing about twelve per cent. of hydrochloric acid. This substance has the properties, among others, of being soluble in alcohol and of forming compounds ("double salts") with mercuric chloride. That recommended for hypodermic use contains twenty five per cent. of the mercury salt. It has been used in seventy cases by Dr. Huefler in the clinic of Professor Struempell, of Erlangen. Each of the patients received about twenty injections of two-thirds of a grain, corresponding to one-sixth of a grain of corrosive sublimate, and from the results obtained the author regards the mercurial as prompt and reliable in action. He did not observe any irritation or formation of pus at the points of injection. In *The Lancet* of October 11, 1890, it is stated that Dr. Selenew has made comparative trials of the advantages of several mercurial salts for hypodermic use, under the direction of Professor Stukovenkow. He has recently obtained considerable success by using the succinimide, a salt which was originally recommended for the purpose by Dr. Vollert and was used in Professor Wolff's syphilitic clinic in Strassburg two years ago in doses of about one-sixth of a grain. Dr. Selenew employed larger doses (one-quarter to one-third of a grain) in a solution of the strength of one per cent. The injections, of which nearly a thousand were given altogether, were usually made into the cellular tissue of the back or buttocks. In some cases a daily injection for twenty-four days sufficed to cause all the syphilitic appearances to disappear; in most of the cases the treatment had to be carried on for about a month, and in one case for forty days. Thirty-three patients in all were treated. In six the gums became affected. In only one was the pain at the seat of puncture at all severe; usually there was no pain at all. In one case there was abdominal pain and diarrhœa, which lasted for five days. Out of twenty-four cases of primary syphilis which remained under observation for seven months only three developed secondary symptoms, and one of these was that of a man addicted to drink. Comparing the results in preventing secondary symptoms with those obtained by the injection of other mercurial preparations, the succinimide appears to be about as efficacious as the yellow oxide, and very much more so than the alaninate, the salicylate, or the so-called gray oil. Dr. Selenew looks upon the succinimide as a mild and valuable preparation, which may be very useful in primary and secondary cases of no great severity, especially in women and children, because of its slight tendency to cause local irritation. In severe cases a more active preparation, as the yellow oxide, the perchloride, the salicylate, or the oxybenzoate, should be preferred.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 13, 1890.

REPORT OF THE SURGEON-GENERAL OF THE ARMY.

THE annual report of Surgeon-General Moore for the year 1889–90, contains an unusual amount of interesting information regarding the department under his charge.

The sick-rate during the year has been a little higher than ordinarily, viz., 44.12 per 1,000 of strength, as compared with 41.91 in 1888–89. The mortality-rate, however, is lower, being but 6.33 as against 8.15 in 1888, and 9.52 during the decade.

The German army alone among European armies has a lower death-rate than our own, it being 2.95 per 1,000.

The prevalence of syphilis in the United States and other armies is a fact which always calls for serious attention.

Dr. Moore says that the discharge-rate from our army for syphilis is extremely high (3.52 per 1,000), while in Germany it is only 0.03 per 1,000, and in the English and French armies not much higher.

This difference is so marked as to merit a word of explanation. "The high rate of our troops is not due to the greater prevalence of these diseases among them. Venereal diseases take first place among the causes of admission in Great Britain and Italy, while they do not form even one of the five prominent causes among our men. The admission-rate of the British army is 253 per thousand men, equivalent to every fourth man affected, while the rate among our troops is 85, equal to one man in twelve. Nevertheless, we discharged 96 men on account of these diseases from our army of 25,000, the British 70 from their home force of over 100,000, the Italians 2 from their army of over 200,000, and the Germans 12 from their strength of nearly 400,000.

"Several causes combine to make discharge for syphilis more frequent in our army than in the European services. Modes of treatment and their results are not concerned in the explanation. The economic side of the question appears to determine the matter. The armies of Europe are large, representing in many instances the maximum strain which their respective countries are capable of bearing, and they cannot afford to throw out men who may be put to use in an emergency. Our army, on the other hand, is so small that there is no difficulty in securing its complement of physically qualified men."

There are at present 164 medical officers in the service.

An army medical examining board was convened in New York City on October 1, 1889, and April 28, 1890, and remained in session during the respective months. The following is a recapitulation of the work performed by the board during its sessions:

Number of candidates found qualified	9
Number of candidates rejected	17
Number of candidates rejected, physical disability	7
Number of candidates who withdrew after partial examination	3
Total number examined	36

The following table shows the condition of the medical museum:

Total number of specimens in museum, June 30, 1889	27,982
Exchanged or discarded during the year	12
	27,970
Total number received during the year	1,315
Total number in museum, June 30, 1890	29,285

There were added to the library during the year 3,935 medical books, transactions, and volumes of journals, 2,286 medical theses, 8,876 medical pamphlets, making a total of 11,162. The total number of volumes in the library is 97,886, while the theses and pamphlets bring up the total to 149,077.

OVER-PRODUCTION OF MEDICAL MEN.

THAT trite, old, much-discussed query, "What becomes of the pins?" might be paraphrased into "What becomes of the doctors?" There has recently been issued the "Annual Report on Medical Education, Medical Colleges, and the Regulation of the Practice of Medicine in the United States and Canada," compiled by that most excellent authority, Dr. John H. Rauch, secretary of the Illinois State Board of Health. The book contains much food for reflection; good solid food, too, which it behooves the trustees of medical colleges and also State legislators to take in and digest. Then they would see and hasten the coming of the better time, near at hand, when medical education will be on a higher plane than now, when there will be no more diploma mills, and when it will require good brains, hard work, and a fitness for the physician's high calling, to get through the most lenient of medical colleges. The first reflection that comes to the reader of the report, however, is one of surprise at the immense number of physicians turned loose on an unsuspecting public every year. For the session of 1888–89, there were 4,337 graduates in medicine in the United States, with almost 300 in Canada. When it is considered that this is a decrease from the number of the preceding session, the query comes, where do they all go to? Then the mind asks how many are fitted for their work, and how many make a success of life, either in a monetary or scientific sense. Opinions will differ. The fact is there is a flood, an avalanche, of young M.D.'s every spring, a veritable over-production—an over-production that is beyond the control of tariff tinkers. That control is vested in just two sets of men, trustees of colleges and State legislators. It is such an easy matter to become a physician—in some colleges a simple payment of fees and an attendance (?) on two courses of lectures of twenty

weeks each—that many impecunious men, with little brains and less conscience, take advantage of the diploma mills and proceed to fleece the American public, which, in many things, apparently likes nothing better than being humbugged. Other men, without this mercenary spirit, perhaps, enter the profession when they are totally unfit by lack of general education to cope with its solemn duties. Nevertheless, they find little difficulty in obtaining diplomas, and still less in finding a State whose authorities will permit their residence and practice. This deplorable state of affairs is recognized by all, and slowly but surely there is a popular sentiment arising that will force colleges and legislatures to make the requirements for practice more stringent, and in so doing, elevate medical education to that high pedestal which it deserves. That this time is coming, as stated above, is plainly indicated in Dr. Rauch's admirable report. It shows that there has been greater progress in the direction of a higher medical education during the college year 1888–89 than for any similar period in the history of the country, and greater than in the preceding half decade. The courses of instruction were increased in many colleges, notably Clark and Johns Hopkins Universities; the number of colleges requiring a graded course increased during the year twenty-five per cent.; an act was passed in New York State requiring a preliminary examination, by the regents of the State University, of all students about to enter on the study of medicine; there was an increase of six per cent. in the number of colleges requiring preliminary examinations; and medical practice acts were passed in Florida, Tennessee, and Oregon. There is no doubt that the popular sentiment favorable to the higher education of the medical student is rapidly growing, and will in time crush all its opponents.

THE MAN AND THE BULL.

THE *Medical Age* discusses at length the subject of doctors' fees and doctors' bills. The editorial tone is sad, and somewhat reproachful withal; especially in reference to the following reminiscence:

"We recall," says the *Age*, "a man of wealth, and who still lives in luxury, no expense being too great where his own gratification is concerned; who squanders money 'like water' in his political projects; who always demands a trifle more than the current value when he condescends to render a service; and who likewise requires the closest and most personal attention on the part of his family physician. He is no way chary in calling upon the latter at all periods, convenient or inconvenient, and needlessly detaining him for hours. Yet this man never liquidates his bill save at intervals marked by years, and when it requires three figures for enumeration of the total, and then, without any consideration of interest, invariably demands a discount of ten per cent. or more. He tendered a consulting physician, from a neighboring city, $30 on one occasion, and on another, $100 to a veterinarian, from a like distance, called to see a *prize bull*. The charges made by his medical attendant are always reasonable, and exactly the same as those to his next door neighbor, who commands less than one-tenth the capital and luxury."

Now, we are not so much disposed to censure the patient in the above case as the modest and humble gentleman who attends him. The rich patient pays as he does because he finds he can do so. Let the doctor double his fees and collect them promptly. People are very apt to believe that things are worth no more than is asked for them. The doctor should render good service and demand good payment; and not worry because a veterinarian gets a bigger fee than he does.

THE CARE OF LEPERS.

THE question of suitable provision for the care of leprous persons is one that the people of the United States will be called upon to consider, and that comparatively soon. It is for the general Government to prevent the incoming of such diseased persons, but upon the authorities of the individual States must fall the burden of preventing the immigration of the unclean ones from neighboring States, and of providing for the care of those already among us, and those who from time to time may fall victims.

Although many problems yet remain to be solved, certain things may be accepted, and these merit our attention. The leper must be separated from the healthy community, and so securely isolated that there will be no possibility of his return to his friends; he must be clothed, and fed, and provided with medical treatment and nursing. For a time he has a right to demand employment, and for all the time that he may live, certain diversion. His social status must also be considered: Shall not a leper be prohibited from marrying a healthy person? Shall he be permitted to marry another leper? How shall the offspring of such unions be provided for? Shall a wife be allowed to accompany her diseased husband, and a daughter her diseased mother, into the leprous community, to care for them so long as they may live, and shall they then be allowed to return to the society of healthy persons? These and many other questions must be solved and provided for by law. If a leper be discovered to-day in this community, what can be legally done with him? How can the community be protected?

Mr. E. H. Plumacher, Consul at Maracaibo, has recently made a report to the State Department at Washington, upon leprosy in Venezuela, and from it we may obtain many valuable hints. An island, four miles from the city of Maracaibo, has been set apart for the isolation of the incurables. A suitable building has been provided for them, and another for the attendants. To those who have sufficient means to build cottages land is given. Water-works have been provided, furnishing not only a sufficient supply for cleanliness of persons and quarters, but also sufficient for irrigation of the land devoted to agriculture. A means of employment is thus provided for those able to work and desiring occupation. The island has been artificially stocked with game, and a reading-room, library, chapel, and occasional musical entertainments are provided. Marriages between diseased and healthy persons are prohibited, but sound wives have been allowed to accompany diseased husbands, and have lived with them through the last stages of this loathsome disease; and daughters have accompanied mothers and cared for them to the end, and have then returned to the world, where they have continued to live healthy mothers of healthy families. For the sake of the moral discipline

of the settlement, and under the belief that such unions would be fruitless, marriages have been permitted between diseased persons. Two children have, however, been born of such unions, and so far neither of these children has shown evidences of the disease; and one of them having reached the age of fourteen years, having lived all that time with his leprous parents, has been pronounced clean and has been allowed to return to the world.

A NEW METHOD OF TREATING ANEURISMS.

Dr. William Macewen, of Glasgow, has recently added another to the long list of procedures intended for the relief of aneurisms. He thinks that former methods, such as galvano-puncture, introduction of wire, catgut, etc., have all been deficient, in that they produced only red thrombi, which can be absorbed or washed away. He aims, therefore, to produce in the aneurisms a white, hard thrombus. This he does by introducing a long, sharp needle and scratching the internal surface of the tumor, thus producing a proliferation of leucocytes. His description of the technique of the operation is as follows:

"The instrument employed is a pin of sufficient length to completely transfix the aneurism and to permit of manipulation within it. Its calibre ought to be as fine as possible, the strength being only sufficient to penetrate the coat of the aneurism and the intervening tissues. This cylindrical pin tapers to a point, like an ordinary sewing-needle, and has on its opposite extremity a somewhat rounded head. As the coats of aneurismal sacs vary in thickness, these pins must be made of various calibres, as those which may pass readily through one aneurismal sac may not pass through others with thicker walls. They ought also to be finely polished, not only to facilitate their introduction, but to help to render them aseptic.

"Before performing the operation the skin over the aneurism ought to be carefully cleansed and rendered aseptic. The aseptic pin ought then to penetrate the sac and pass through its cavity until it comes in contact with the opposite side. It ought to touch and no more Then one of two methods may be employed: either to move the pin over the surface of the inner wall so as to irritate its surface, or to allow the impulse of the blood-current playing on the very thin pin to effect the same object. If the wall penetrated by the pin on introduction be dense, the former method will be preferable, as the force of the blood-current produces such a feeble action on the thin pin as to be insufficient to move it to and fro, while it is firmly grasped by the dense wall. After acting thus for ten minutes at one part, the point of the pin, without being removed from the sac, ought to be shifted to another spot, and so on until the greater portion of the internal surface opposite to the point of entrance has been touched; this ought to be done in a methodical manner. A single insertion of the pin through the aneurismal sac into its interior may be sufficient to enable the point of the instrument to come into contact with the greater part of its internal surface, but in some cases puncture from various sides of the external wall may be necessary, so as to reach portions of the tumor which cannot be attacked from the first puncture. While the pin is in the aneurism it is surrounded by a portion of aseptic gauze, or moistened with an antiseptic solution. When it is withdrawn from the aneurism, the part ought to be covered with moist antiseptic dressing, preferably a watery solution of carbolic acid, which ought to be maintained for several days. The period a pin may remain in an aneurismal sac without doing damage is perhaps dependent on the individual and the state of the aneurism, but it ought never to exceed forty-eight hours. It is questionable whether all the necessary advantages derivable from the irritation of the wall of the aneurism could not be produced within a few hours."

Dr. Macewen says that his method is different from the old acupuncture procedure. He reports four cases of abdominal and thoracic aneurisms, with a cure of three.

FASTING.

In connection with Professor Moleschott, of Rome, Professor Luciani, of Florence, made a careful study of the "Hunger Virtuoso," Signor Succi, during his thirty days fast some two years ago. The results of their work are published in a monograph entitled "Fasting: Studies and Experiments upon Man," printed in Italian and German.

The subject of their experiments is now in this city, and, as we write, is approaching the fortieth day of his fast. He has come to this country on a hunger tour, and having broken the record in this city, will, later, take in Chicago and the Western circuit.

The man, from all accounts, is not an impostor, and this makes his history and performances decidedly interesting. Succi is an Italian, thirty eight years of age, the son of a sailor, and in his early life he followed the sea as a fisherman. He is not an educated, or in any sense a scientific, man. His life has been a wandering one, he having travelled in Africa and visited various Eastern countries. He has, it is said, been twice for a short time in a lunatic asylum; but he asserts that his commitment was due to his announcements that he would and could fast for thirty days. He has no delusions or even any extraordinary psychological theories, though a believer in "spiritism" and psychic force. He is said to have some anomalies of the skull; and his peculiar performances and choice of occupation show that he is an illustration of one of the abortive forms of paranoia.

Signor Succi, when not starved, is a man of strong muscular frame, with little subcutaneous fat, and weighing about one hundred and forty-seven pounds. During his thirty days' fast in Italy he lost 6,161 grammes, or about thirteen pounds. During his first thirty days of fasting here he has lost considerably more. He drank at that time an average of 577.5 grammes of water daily, which is about the amount he takes now.

Luciani states that he had "firm muscles, a good deposit of subcutaneous fat, a very slow tissue-change, and, above all, an extraordinary force of will." The Italian professor seems to think that by voluntary exertion Succi is able to slow down the metabolic processes, just as some peculiarly endowed persons can slow down the heart. It is upon this interesting point that Luciani particularly dwells; and he finds in Signor Succi a proof of the regulating influence of the nervous system over the functions of heat-production, respiration, hepatic action, etc.

There seems to be something new learned, therefore, from the fasting of human beings not discoverable by studies upon animals. Certain it is that no mammal can live as long without food as Succi proposes to do.

The Italian faster, after thirty-three days, has a slow pulse of from 60 to 70, urine of about normal specific gravity and moderate in amount. He drinks water, and daily takes fifteen or twenty drops of an elixir which undoubtedly contains some opium.

THE LYMPH INOCULATIONS IN THIS CITY.

A LIMITED supply of the Koch lymph has at last reached New York, and, as will be seen by our accounts in another column, no time has been lost in making inoculations. Very properly hospital patients only have been selected as subjects of the experiments. The Hospital for the Ruptured and Crippled was the first to use the lymph, and following it in turn were the St. Luke's and Mount Sinai Hospitals. All the cases were chosen as proper ones for the tests and were examined with great care accordingly. There need be no fear that the Koch method of treating tuberculous affections will not have a fair and impartial trial under the care of competent observers, and that perfectly impartial reports will be made.

While the profession of this city and elsewhere is not prepared to express any opinions upon the results, the investigations will be carried out with a fairness which will commend themselves to every earnest seeker after truth. It is safe to say that no topic connected with the prevention and cure of disease has so thoroughly engaged the interest of medical men, since the discovery of Jenner. It should be considered a compliment to the distinguished Berlin investigator that almost on his dictum alone, backed by his well-earned reputation for candor and truthfulness, the attention of the profession has been so strongly and earnestly directed to the novel treatment of tuberculosis. To few men would a similar confidence be accorded under the present circumstances of dealing with a preparation the composition of which is so persistently kept as a secret. Whatever may be the present excuse for withholding information concerning the makeup of the lymph, it is to be deplored, in the interest of science and humanity, that there should be any barrier whatever to its extended manufacture, and its widest possible dissemination. We have no doubt, however, that the real nature of this now mysterious fluid will shortly be made known—at least the distinguished discoverer owes it to the profession to do so in view of the implicit faith with which its members have received his statements, and the generous spirit with which they have interpreted his motives. So far, in this city at least, we have to congratulate ourselves that the lymph is now within reach and that we can see for ourselves what can be done with it.

It will of course be impossible to predicate any direct results in the cases treated during the past weeks. Aside from the fact that some of the phenomena of temperature reaction and increased hyperæmia of affected parts have shown themselves, nothing of real value as to cure can be determined within months from the present time. With so many observers on the alert it is safe to say that the tests will be very thorough and conclusive.

News of the Week.

Hospital Difficulty.—The brethren at Ottawa, Canada, are experiencing the rigors of hospital management, but appear to be standing manfully together. At a recent meeting of the Board of Directors of the Protestant Hospital, Dr. A. F. Rogers was dropped from the medical board without notice and without stated cause, and Dr. Kidd was appointed in his place. The seven other members of the medical board have resigned, and with them the newly appointed member, Dr. Kidd. As yet no one has been found to accept appointment to the vacant places. Unfortunately, this is not the practice in New York.

The Medical Society of Missouri Valley will meet at Kansas City on December 18 and 19, 1890. An interesting programme, consisting of twenty-two papers, has been announced.

Dr. F. Harman has been elected Superintendent of the Longview Asylum, at Cincinnati, O., in place of the late Dr. Miller.

Dr. C. B. Chesher, of Paulding, O., has been appointed Superintendent of the Cleveland Insane Asylum, in place of Dr. Janin Strong, who will retire on January 1, 1891.

Dr. Ralph Jackson died December 3d at his residence, 4 West Fourteenth Street, Dubuque, Ia., aged eighty-one years. Dr. Jackson was born in England and came to Dubuque nearly forty years ago. Dr. Jackson was a man of pure character and sterling integrity, and the shadows of his declining years were brightened by the respect and esteem of the community in which he lived.

Dr. J. B. Jones, Medical Superintendent of the Western Hospital for the Insane, Mississippi, died November 15th of consumption. He had been in charge of this institution since its inception, and was a live and efficient officer, always careful of the State's interests and attentive to duty. His remains will be buried at McKenzie, his former home.

Swallowed a Gold Safety-pin.—A patient of Dr. F. H. Wiggin, aged nine months, swallowed a gold pin, made something like a common safety-pin, an inch and a half long. The pin was open when swallowed, and was passed, pin point up, without harm, fifty-four hours later.

The Review of Insanity and Nervous Disease is the title of a new quarterly, edited and published by Dr. J. H. McBride, of Milwaukee.

An Infant Medical Phenomenon.—The Southern Medical Society in Atlanta has recently elected to honorary membership a boy phenomenon, who though only five years old has already acquired a knowledge of anatomy which is fully equal to that of most graduates of medicine. He is a regular attendant upon the anatomical lectures at the Southern Medical College, though he is himself, at present, a matriculate of the kindergarten department of a local academy, where we are informed that his long, golden curls, rosy cheeks, intelligent blue eyes, and amiable disposition make him a general favorite.—*Boston Medical and Surgical Journal.*

The Late Dr. Emil Neumer.—On November 4, 1890, a joint meeting of physicians and laymen connected with the St. Mark's Hospital and the German Poliklinik, respectively, was held at the residence of Dr. Beck, 187 Second Avenue. The late Dr. Emil Neumer had been connected with said institutions for a number of years. The following resolutions, submitted by a committee, were unanimously adopted:

Whereas, Our friend, Dr. Emil Neumer, supervising physician of the St. Mark's Hospital and a member of the German Poliklinik, has departed this life; and,

Whereas, By his untiring zeal and singleness of purpose he earned the good-will and gratitude of all connected with both institutions; and,

Whereas, His self-sacrificing labors contributed largely to undermine his health; be it

Resolved, That the physicians and members of St. Mark's Hospital and of the German Poliklinik, at a special joint meeting assembled, do express their deep sense of grief at the untimely loss of their friend and fellow-worker, Dr. Emil Neumer, and further express their heartfelt sympathy with, and tender their condolence to, his bereaved family; and,

Resolved, That a copy of these resolutions be published in the medical journals.

The Committee: For the St. Mark's Hospital—Dr. C. Beck, Dr. H. J. Boldt, and Mr. F. A. Botly;

For the German Poliklinik—Dr. H. Busche, Dr. S. Kohn, and Dr. Geo. W. Rachel.

DR. H. J. GARRIGUES, *Chairman*,
MR. MAX RUTTENAN, *Secretary*.

The Ohio Humane Society.—In the State of Ohio some philanthropic people have obtained articles of incorporation for an organization known as the Ohio Humane Society, the functions of which are to see to the effectual enforcement of all laws enacted for the better protection of helpless women and children, as well as that of dumb animals.

Chigger.—Dr. H. M. Whilply has been making further investigations of the chigger (*Leptus Irritans*). It is distinct from the South American and West Indian insect of the same name, which is of the flea family (*Pulexæ*). It has not been found in latitudes north of the fortieth degree, nor in the Far West. It does not limit its diet to human flesh, but has been found on chickens and on the common house-fly.—*Popular Science News*, July, 1890.

Ungrateful Republics.—Under the title of "Republican Cruelty," and *à propos* of the splendid reward of his Government to Dr. Koch for his discoveries, the *Boston Transcript* writes, sarcastically: "This is all very well for these effete monarchies, but in a republic of free men no such nonsense would be permitted. Witness our treatment of the discoverer of ether." Commenting on this, Dr. W. R. Hayden, of Massachusetts, writes to the same paper, saying that "our great Government was never more cruelly unjust, or did itself more discredit, than in its treatment of poor Dr. Morton, for his discovery of anæsthesia by etherization, in rejecting his claim for compensation. Dr. Morton's discovery outranks in value any other discovery ever made to prevent human suffering." He suggests that our Government should build a suitable memorial at Washington, D. C., to the man whose sublime mission was to prevent pain, not inflict it; or if such recommendation should not be deemed advisable, suggests that a subscription of fifty or one hundred thousand dollars be raised from the profession and the people to build the monument, agreeing on his own part to subscribe one thousand dollars.

A Mother at Sixty.—An old Swedish woman, living near Lapeer, Mich., recently gave birth to her first child after having been married thirty-eight years. The woman claims to be sixty years of age. The baby, a boy, weighed only three pounds at birth and was shrivelled, but otherwise healthy. The woman says that she was born when her mother was fifty-two years of age, and that her grandmother gave birth to twins at the age of sixty-three.

Why is this Necessary?—An effort is being made in Georgia to prohibit physicians, and prescription-clerks in drug establishments, from pursuing their professional calling, who may become intoxicated from the use of liquors and opiates.

Afro-American National Medical Association.—Owing to the refusal of Southern Associations to admit colored physicians into their meetings, a number of prominent colored physicians of the South have issued a call to all regular negro practitioners of the South and other sections to meet in Little Rock, Ark., December 19, 1890, to form an Afro-American National Association.

Transfiguration Clinic.—During the past year a medical service with the above title has been conducted in connection with the other charity work of the Rev. Dr. Houghton's "Little Church around the Corner," and the first report has just been printed. The clinic, located at No. 6 Pacific Place, West Twenty-ninth Street, between Sixth and Seventh Avenues, is hardly what its name implies, inasmuch as the patients are not used for purposes of teaching. It has several novel features which make it unlike any other clinic or dispensary in the city. It is intended only for the poor of the parish of the Church of the Transfiguration; each patient is treated with the same privacy and consideration that would be given in private practice; every case is investigated as to its ability to pay, and only the deserving poor are treated, and these are expected to pay something for the medicine if they are able. Cases are visited at their homes when necessary by the physician in charge of them, and not by a regularly appointed visiting physician, who knows nothing about the case and has no personal interest in it. Nursing is supplied when required, and food is sent out to those who need it. It is believed that nursing and food often play as important a part in the cure as do doctoring and medicine. The attending staff consists of Drs. Edward Quintard, Charles T. Parker, Richard Kalish, Robert C. Myles, Lewis R. Morris, Rowland G. Freeman, Calvin L. Harrison, and Brentano Clemens.

New Hospitals.—A new hospital, to contain forty-eight beds, is to be built at Fall River, Mass. A lying-in hospital is to be erected in connection with St. Paul's Orphan Asylum, at Pittsburg, Pa. A $50,000 hospital is planned for Macon, Ga., and another for Brunswick, Ga.; and at Omaha, Neb., the Sisters of Mercy have well under way a hospital building for the accommodation of four hundred patients.

The Influenza in Massachusetts.—The Secretary of the Massachusetts State Board of Health closes his annual report with the following interesting facts about last winter's epidemic: "1. The first appearance of the influenza in Massachusetts as an epidemic, in the past season, may be stated to have been on December 19 or 20, 1889, and the place of its first appearance was Boston and its immediate neighborhood. 2. It increased rapidly in the number of persons attacked, and reached its crisis generally throughout the State in the week ending January 11, 1890, after which date it gradually declined in severity, and had nearly ceased as an epidemic by February 10th; so that the duration of the epidemic was about seven weeks. It reached its crisis earlier by several days in Boston than in the smaller cities and the remoter parts of the State. Its course was still later in Nantucket, Dukes, and Barnstable Counties. 3. The ratio of the population attacked was about forty per cent.—or more exactly, as indicated by the returns, thirty-nine per cent. —or about eight hundred and fifty thousand persons of all ages. 4. People of all ages were attacked, but the ratio of adults was greatest; of old people next, and of children and infants least. 5. The weight of testimony appears to favor the statement that persons of the male sex were attacked in greater number and with greater severity than females. 6. The average duration of the attack (acute stage) was from three to five days. 7. The predominant symptoms were mainly of three general groups—nervous, catarrhal, and enteric, the last being much less common than the others; the special symptoms most observed in the nervous group being extreme depression, pain, and weakness; in the catarrhal group, cough, dyspnœa, and coryza; and in the enteric group, nausea, vomiting, and diarrhœa. 8. The chief diseases which followed in the train of influenza, and were intimately associated with it, were bronchitis and pneumonia. Phthisis, when already existing in the victim of the attack, was undoubtedly aggravated; and, in many cases, a fatal termination was hastened. 9. The ratio of persons attacked in industrial and other establishments employing large numbers was about 35.5 per cent., or less than that of the population at large. That of the inmates of public institutions was still less—twenty-nine per cent. 10. The ratio of persons who were obliged to leave their work on account of illness from influenza was about twenty-seven per cent. of the whole number employed. 11. The average length of their absence from work was five days. 12. Special occupations do not appear to have had a marked effect in modifying the severity of the epidemic upon operatives in such occupations. While the atmosphere may constitute one important medium of its communication, human intercourse also suggests itself as an equally important factor."

Dr. Samuel Lewis, of Philadelphia, died November 26th, at Bryn Mawr. Dr. Lewis was born on the island of Barbadoes, West Indies, in 1813. He studied medicine in the University of Edinburgh, from which he was graduated in 1840 with the degree of M.D.

Prize of the New York State Medical Association.—Dr. J. G. Orton, ex-President of the New York State Medical Association, has offered a prize of $100 for the best short popular essay on some subject connected with practical sanitation, under the following conditions: 1. Competition to be open to all. 2. Essays to be forwarded to the Secretary of the Association, Dr. E. D. Ferguson, Troy, N. Y., not later than August 1, 1891, accompanied by the name of the author under separate seal. We trust that the State Association will be more successful than the State Society or the New York County Medical Society. The latter organization has not found a beneficiary for its $100 gold medal, if we remember correctly, for eight years.

The Attractiveness of Chicago to Physicians.—It was stated at the recent annual meeting of the Illinois State Board of Health that at no time since the organization of the board had there been such an influx of physicians into Chicago as within the preceding three months, during which time more than two-thirds of the licenses issued to practise medicine were to practise in Chicago. It was also stated that never before had there been such a number of quacks trying to get a foothold in that city. This was partly attributed to the attractiveness of the prospective fair, and partly to the increase of population. —*New York Medical Journal.*

Bequests to New York Hospitals.—By the will of the late Daniel B. Fayerweather, of this city, the following bequests are made to hospitals in this city: Presbyterian Hospital, $25,000; St. Luke's Hospital, $25,000; to the Manhattan Eye and Ear Infirmary, $25,000; the Woman's Hospital, $10,000; Mount Sinai Hospital, $10,000.

Dr. James L. Stewart, one of the most distinguished surgeons in Pennsylvania, died December 3d, at Erie, at the age of sixty-six. He had been Vice-president and President of the Pennsylvania State Medical Society, was a member of the American Medical Society, also a member of the International Medical Association. He had been a member of the American and International Executive Committees, and was a conspicuous figure in securing legislation, both national and State, for medical institutions.

A Novel Suit.—Judge Schuyler, of Easton, Pa., has rendered his decision in the novel lawsuit he heard at Stroudsburg some time ago, in which Dr. Josephus Williams brought suit for damages against Dr. Amzi Lebar and Dr. J. H. Shull. The doctors pronounced Dr. Williams insane, whereupon he was confined in the Danville Insane Asylum in 1876. The doctor secured his release from the asylum, and brought suit for damages on the ground that the defendants negligently and falsely signed a certificate to the effect that he was insane. Dr. Shull subsequently settled his suit with the plaintiff. Dr. Lebar refused to settle, and now wins. Judge Schuyler's decision is, that while it was not proved that the plaintiff was insane at the time of imprisonment, no negligence on the part of the defendant was shown, and a verdict was rendered in favor of the defendant.

Iowa is the Place.—If one wishes to secure immortality he had better go to Iowa, where, according to the State Board of Health's estimate the death-rate is only four per thousand annually. The most favorable estimate of mortality in the most ideally sanitary community has heretofore been supposed to be only four per one thousand.

A New Treatment for Prolapse of the Rectum, introduced by Dr. S. D. Powell, and but little known, consists in rolling in and strapping the buttocks together with two strips of adhesive plaster, extending sufficiently forward to secure a good hold. The child (or adult) defecates with these in position, is thoroughly cleansed after the act, and new strips applied. This method, which in the hands of the inventor has never failed, is based on the fact that thereby the relaxed sphincter is elevated and supported during the strains put upon it while the child is at play and protected from the lateral traction occurring in the squatting position assumed in defecation. It and the parts above gradually regain their contractile power and ultimately become competent to fulfil their function normally.—*N. Y. Correspondence Peoria Med. Monthly.*

The American Association for the Cure of Inebriety, which has celebrated its twentieth anniversary, began a series of monthly meetings in the hall of the New York Academy of Medicine. The first meeting was held December 10th.

Biography of Dr. Robert Koch.—Dr. Koch was born forty-seven years ago at Clausthal, in the Hartz Mountains, he was educated and graduated at the University of Gottingen. Shortly after taking his degree he established himself in a village near Hanover and began to practise as a physician. Finding, however, that it was impossible to make both ends meet, he migrated to Rackwitz, a little malarious town in Prussian Poland, which he subsequently deserted for Wollstein. It was while there that his name came before the public in 1880 as an expert in connection with the famous Speichert poisoning case. The conviction of the prisoner in this *cause célèbre* was entirely owing to the remarkable analyses and medical testimony of Dr. Koch, which attracted widespread attention by reason of their profound erudition. Later he made some remarkably accurate studies in septicæmia. In 1882 he first made the great discovery that tuberculous diseases were due to the existence of bacilli. In 1883 his labors were interrupted by his being placed at the head of the medical commission dispatched by the German Government to Egypt and India for the purpose of making researches into the origin and the causes and prevention of cholera. It was while at Calcutta that he succeeded in discovering the like germ of cholera. On his return to Germany he was rewarded by the Government for his researches with an honorarium of 100,000 marks, with the rank of Privy Councillor, and with the Rectorship of the Imperial Institute of Hygiene.

Longevity.—The medical profession is not usually considered one favorable to extreme longevity, but a retired naval surgeon—Deputy Inspector-General Robert McCormick—has just died at the age of ninety. He was a pupil of Sir Astley Cooper, and was surgeon to several arctic and antarctic expeditions. His arctic and antarctic experiences extended from 1827 to 1853. In the former year he accompanied Sir Edward Parry in the Hecla in his attempt to reach the north pole. He was chief medical officer and naturalist to the antarctic expedition of 1839–43, and commanded the boat expedition in search of Sir John Franklin in 1852.

MORE EXPERIENCES IN BERLIN WITH KOCH'S LYMPH.

By Direct Cable to the Medical Record.

(From a Staff Correspondent at Berlin.)

Berlin, December 9, 1890.

Koch's discovery continues to be the main point. The possibility of making animals immune against diphtheria increases Koch's glory. The audiences and clinics are still crowded, but not so much as last week. As to the results of Koch's treatment, the time of observation has been too short in order to prove the therapeutic value, but in localized, accessible, and visible tuberculosis, viz., tuberculosis of the joints, bones, skin, and larynx, the efficacy of the remedy has been proven. Bergmann and Bardeleben demonstrate in their clinics patients with stiff tubercular joints which become movable, and secreting fistulas which heal completely after a few injections.

In the last Charitisitzung, December 5th, Henoch read a paper on the administration of Koch's remedy. In children he has used the remedy in eleven tubercular patients since fourteen days. All have given the characteristic reaction. He began with 0.0003 c.c., slowly increasing the doses. In meningitis tuberculosa he would be afraid to use the injections on account of hyperæmia of the brain, but even in other cases we must be very cautious with the administration of the remedy.

Professor Ewald read a paper on Koch's remedy in phthisis. In advanced cases of phthisis he would not use the remedy. In most of the cases there was an amelioration of appetite, in several the night-sweats ceased.

Dr. Litten presented a female patient who had been infected by nursing her phthisical sister. She had used the handkerchief of her sister. Lupus on the nose and tubercular ulcer on the gingiva. After the injection of one milligramme, temperature 40° C.; the gingiva reddened intensely and decayed and new miliary tubercles arose. The efficacy of the remedy consists in acute decay and necrosis. The decayed tubercles give the fever.

Last night, December 8th, in the meeting of the Gesellschaft für Offentliche Gesundheitspflege, Linder, Fraenkel, and Krause read papers on their experiences with Koch's remedy, containing the same ideas which have been already described. In the tubercular larynx Krause said the healing process by the injection can be observed from day to day.

The lymph is very scarce, and the foreign physicians will have to wait several weeks before being supplied with it. Leyden told me that he has lymph in the Charité, but he is not allowed to use it on his private patients.

The letters asking for lymph must be addressed, Dr. Libbertz, Lueneburger Strasse, 28, Berlin. The cost of one vial is twenty-five marks. Last week there arrived from America, Drs. Aronson, Bettins, and L. Weiss, from New York, and Dixon, from Philadelphia.

THE INOCULATIONS OF PROFESSOR KOCH'S LYMPH IN NEW YORK.

THE first inoculations of Koch's lymph in New York were made Tuesday at 5.30 P.M., at the Hospital for Ruptured and Crippled, by Dr. Allan McLane Hamilton. One milligramme was used, properly diluted with sterilized water, and injected by means of the Koch bulb-syringe, a description of which appeared in our last issue.

On Tuesday morning, December 9th, Dr. Hamilton notified Dr. Gibney that he had a small vial of Koch's lymph, and would like to employ it in a case of tubercular meningitis. Dr. Gibney replied at once that he fortunately had no such case at present in the hospital, but had many cases of bone tuberculosis, and would be glad to have him call in the afternoon to make such experiments as he desired.

The following is the preliminary report made by Drs. V. P. Gibney and Allan McLane Hamilton:

CASE I.—At 5.30 P.M., in the presence of two members of the Consulting Staff, Drs. J. H. Ripley and L. E. Holt, Dr. W. R. Townsend, Assistant Surgeon, Dr. George De F. Smith, and the members of the House Staff, the first inoculation in a public institution in this city was made upon a boy, ten years of age, who had been under treatment in the hospital for several years for tubercular ostitis of the right hip. This case was selected because his general health was good, because the sinuses had closed, and because it was believed that a cure was complete. Dr. Ripley examined his lungs with negative result. His pulse was 76; respiration, 20; and temperature, 98⅘° F. The syringe had been previously sterilized and 2 minims of the solution, strength 1 milligramme = 5 minims, was injected in the interscapular space by Dr. Hamilton. At 6.45 P.M. his pulse was 80; respiration, 20; temperature, 98⅘° F. At 7.45 P.M., pulse, 76; respiration, 20; temperature, 98½° F. At 8.45 and 9.45 the vital signs were practically the same. At 10.45 his pulse was 72; respiration, 19; and temperature, 99° F. There was no rise of temperature beyond this. He slept well during the night and kept his bed during the following day, Wednesday. He complained of a little soreness about the puncture, and there was a slight area of redness, but beyond this there was nothing that could be construed into a reaction. At 6 P.M. on this date 5 minims of the same solution were injected, and up to the present writing there has been no reaction.

CASE II.—A member of the House Staff was selected as a healthy subject, lungs examined by Dr. Ripley with negative result, and 5 minims were injected in the interscapular space. Careful records were kept during the evening without any positive result. In the morning the doctor reported that he experienced no change whatever, save a little accentuation of pain around some scratches on his hands, produced by plaster work.

CASE III.—December 10th, a boy, aged twelve, typically tuberculous in appearance, in hospital since May, 1889. Excision of knee for tubercular disease had been performed last spring. A large portion of bone had been removed, but sinuses remained and these had been treated with the peroxide of hydrogen. In addition to the sinuses, an ulcer, supposed to be tuberculous, existed on the posterior aspect of the thigh. This case was selected in the hope, also, that the process had been arrested. Dr. John S. Thacher examined his lungs with negative results; injection of 5 minims made at 6.20. A careful record was made every hour preceding and subsequent to the inoculation, from 5 P.M. to 12 midnight. There was no elevation of temperature whatever. This morning, December 11th, the boy reports himself as feeling quite well; complained during the night of pain in his back, which pain prevented him from sleeping; beyond this, no reaction.

CASE IV.—December 10th; girl, aged seven; under treatment since May 23, 1890, for dorsal Pott's disease with abscess about the right hip. This had been opened and treated after Billroth's method. For the past week she has been out of health, had a decidedly "strumous" appearance, and, for the past day or two, has suffered from a phlyctenular conjunctivitis. Her lips are large and flabby and eyes heavy. Dr. Thacher examined the lungs, pronouncing them healthy. At 6.25 P.M. 3 minims of this same solution were injected, the usual records having been made. A 11 o'clock in the evening, the night nurse reported that the child was suffering from "snuffles," was breathing heavily, and was not resting well. The vital signs, however, showed no change. This morning, December 11th, she is resting comfortably, her vital signs are normal, she does not complain of any pain about the site of puncture.

Following these inoculations was one made 11 A.M. Wednesday, by Dr. Francis P. Kinnicutt at St. Luke's Hospital, in the presence of the Visiting and House Staff. The patient was a female with pulmonary tuberculosis, the disease being limited to the extreme apex of the right lung, attended with the evidences of simple infiltration. A large number of tubercle bacilli were found in the sputa. Five and a half hours after inoculation her temperature began to rise, so that at the end of twenty-four hours it reached 101.2° F. There was during this time a slight increase in expectoration, and also in the moisture of the râles.

The first public inoculation of the lymph was made by Dr. A. Jacobi on Wednesday, 12.30 P.M., at the Mount Sinai Hospital. Besides the members of the Visiting and House Staffs there were present several physicians, among whom were Drs. A. L. Loomis, E. G. Janeway, Mitchell L. Prudden, F. P. Kinnicutt, C. L. Trudeau, and George F. Shrady. Eight persons were treated.

Case I. was that of a girl, aged eleven, with tubercular consolidation of both apices. At the end of four hours the temperature rose to 100.6° F. Slight increase of expectoration at end of twenty four hours.

Case II., a female child, aged eight, with chronic tuberculous glands of the neck. Three hours after inoculation temperature commenced to rise gradually until fifteen hours after it reached 103.6° F. There was slight pain at the point of injection, with swelling of the glands of the neck. There were no rigors.

Case III., male, aged thirty, with lupus of face of ten years' standing. Twenty-four hours after injection there was marked redness of the lupus scar. No temperature reaction.

Case IV., male, aged twenty, with lupus of penis. Twenty-four hours after inoculation slight redness about the growth. No temperature reaction.

Case V., adult female with pulmonary tuberculosis. Six hours after injection temperature rose to 100° F., and then gradually subsided.

Cases VI. and VII., adult males with pulmonary phthisis. In one of these the temperature rose to 101.8° F. in the course of nine hours, and in the other to 100.2° F. in twenty-four hours.

Case VIII., a normal case for "control," male adult. The temperature rose, despite the absence of physical signs, to 100.2° F. in twenty-four hours.

In all the cases of tuberculous phthisis tubercle bacilli were discovered in the sputa.

In all the cases mentioned the uniform dose of one milligramme diluted to one gramme in bulk was used, the injections, save in one case of lupus of the penis, being made in the interscapular integument. In the exceptional case mentioned the lymph was introduced under the skin of the left inguinal region.

On Thursday, at 3 P.M., Dr. Kinnicutt gave a public exhibition of the inoculation method at St. Luke's Hospital. Among the medical guests were Drs. Leaming, Prudden, Trudeau, Coe, Keyes, Fox, Lefferts, Weir, Cleveland, Biggs, Bull, Draper, Robinson, Abbé, Dana, and Shrady.

Five patients in all were treated. In each the same dose of one milligramme in a hundredth dilution of sterilized water was inoculated.

Case I., female, aged twenty-two, with lupus of left ear, sent by Dr. George L. Fox. The disease existed for twelve years, and followed the operation of piercing for earrings. No pulmonary complication.

Case II., female, aged twenty; enlarged cervical and inguinal glands of six months' duration. No pulmonary complications. Knee excised by Dr. Abbé for tuberculous disease in December, 1886.

Case III., male, aged thirty-five, sent by Dr. E. L. Keyes, with a diagnosis of tuberculous disease of the prostate, in order that diagnosis might be confirmed by reaction after inoculation.

Case IV., male, aged thirty-five. Tuberculous glands of the neck of two months' duration.

Case V., male, aged twenty-nine years. Lupus of hand, slight evidences of consolidation of left apex.

Dr. A. Jacobi inoculated also on Thursday five additional patients at Mount Sinai Hospital, using one milligramme of the lymph, as before. These cases were respectively as follows: Caries of rib and tibia, caries of the spine, pulmonary phthisis, tuberculous glands of neck and groin, and pulmonary phthisis of both apices.

Up to the time of going to press, Thursday night, no temperature reactions were noted either in Dr. Jacobi's or Dr. Kinnicutt's cases of that day.

Dr. Jacobi also inoculated three cases of phthisis at the German Hospital on Thursday afternoon.

While the laudable and generous rivalry prevails of making the early records of inoculation, it is proper to note that the first inoculation made in America was at New Haven, Conn., on Tuesday of last week. The operator was Dr. Francis Bacon, of that city. He has used the lymph in three cases. One, and the first, was a typical case of lupus of four years' standing, in which two injections were administered, with nearly forty-eight hours interval. The first was of five milligrammes. The apparent effects were so entirely negative that the next injection was made twice as large, *i.e.*, one centigramme. Up to thirty-eight hours after this second injection, the only visible effect was a slightly ecchymosed area about the puncture. No temperature or pulse reaction after either application in this case, and no decided subjective or objective symptoms.

The other two cases were of advanced pulmonary phthisis, in the first of which only half a milligramme was employed on account of the great weakness of patient. The temperature rose one degree within an hour, but subsided within three hours. A second injection of the same amount was followed by the same reaction.

In the third case, which was selected on account of visible laryngeal lesion, the first injection, by Dr. Bacon, was one milligramme. Reaction slight and transient.

The history of these cases is the starting-point for investigation in this and other cities. We shall endeavor to keep our readers duly informed of their progress from time to time. We have thus far given only the barest outlines as matters for reference, trusting that the gentlemen more directly concerned in the treatment of these cases may at some future period furnish the necessary details and results.

A New Medical College in Baltimore.—The newspapers announce the organization of the "Southern Homœopathic Medical College." Twelve chairs and two lectureships were filled by local practitioners, vacancies remaining in the chairs of surgery and operative surgery. This institution, with its hospital, is the outgrowth of a schism in the homœopathic camp. As they are backed by a large and wealthy following, the institution will doubtless meet with an early and substantial success.—*Journal of American Medical Association.*

Obituary.

SURGEON-GENERAL JEDEDIAH H. BAXTER,

WASHINGTON, D. C.

Surgeon-General Baxter died of apoplexy at his residence in Washington on December 4th, aged fifty-three years. His death, just after he had reached the object of his long ambition, and just as he was placed in an office whose duties he was admirably calculated to fulfil, is a sad comment on the uncertainty of human affairs. His untimely end is a hard blow also to his many friends, who expected so much of him in his new field of usefulness.

Dr. Baxter was born in Stafford, Vt., May 11, 1837. In 1859 he was graduated from the academical department of the University of Vermont, and entering the medical department of the same institution, he was graduated M.D. in 1860. Upon receiving his degree he established himself in Washington, but in 1861 relinquished private practice and entered the United States service as Surgeon to the Twelfth Massachusetts Regiment. He was promoted to be Surgeon of the United States Volunteers in 1862, and was brevetted Colonel in 1865. In 1867 he was appointed assistant medical purveyor, and in 1874 was made chief medical purveyor, which office was created expressly for him. In 1875 he received the degree of LL.B. from Columbia University, Washington.

He was a member of the District of Columbia Medical Association, the District of Columbia Medical Society, Public Health Association, American Medical Association, and a corresponding member of the Boston Gynecological Society, and of the Philadelphia Academy of Natural Sciences. He was a contributor to the leading scientific periodicals, and the author of "Medical Statistics of the Provost Marshal General's Bureau."

On August 16th last he was appointed Surgeon-General in the place of Surgeon-General Moore, retired.

SIDNEY ALLAN FOX, M.D.,

BROOKLYN, N. Y.

Dr. Sidney Allan Fox died December 11th, of pneumonia, at 22 Cambridge Place, Brooklyn, in his thirty-fourth year. He graduated from the University of Kentucky, and in 1880 began the practice of medicine in this city. For the past eight years he practised in Brooklyn as a specialist in the treatment of diseases of the nose, throat, and lungs. He had been surgeon of the Brooklyn Elevated Railroad Company since its opening. Three years ago he established the Brooklyn Dispensary at 545 Fulton Street, for the free treatment of patients in his special department. Last summer he participated in the Medical Congress in Berlin as a delegate from the Medical Society of the State of New York. His widow, who is also suffering from an attack of pneumonia, is the only daughter of Congressman-elect William J. Coombs.

Hot Water in a Hurry.—Very often a physician needs hot water in the middle of the night when there are no conveniences at the house of his patient to obtain it. Especially is this apt to be the case in summer time. If there should be a kerosene lamp handy with a chimney having a corrugated top this want can be easily met. Place an ordinary tin cup with a sufficient amount of water upon the top of the chimney. The corrugations let out the heated air so that the lamp will not smoke and the water will quickly become hot. This is often a great convenience, and it is astonishing how quickly the needed hot water can be obtained. As a practical thing it may serve a useful purpose—*Dixie Doctor.*

Society Reports.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Third Annual Meeting, held in Atlanta, Ga., November 11, 12, and 13, 1890.

FIRST DAY, TUESDAY, NOVEMBER 11TH—MORNING SESSION.

THE Association convened in Concordia Hall, and was called to order by the President, DR. GEORGE J. ENGELMANN, of St. Louis, Mo., at 9.30 A.M.

Address of Welcome was delivered by MAYOR GLENN, the response to which was made by DR. R. B. MAURY, of Memphis, Tenn.

How shall we Treat our Cases of Pelvic Inflammation?—DR. R. B. MAURY, of Memphis, then contributed a paper on this subject. The paper gave a comprehensive *résumé* of the pathology of chronic pelvic inflammation, as it has been clearly demonstrated by Bernutz, Polk, Coe, and others, and by the results of abdominal section. This pathology is that of pelvic peritonitis dependent upon tubal disease—not cellulitis. The author declared the term chronic cellulitis a misnomer—a pathological condition which existed only in the imagination of the physician, a term which had been productive of pernicious results in practice, and which should no longer be used in connection with non-obstetric pelvic inflammation.

When the pathology rests upon such positive and abundant evidence, the question might be asked, why reopen a discussion upon it now? Because it is evident, from our society proceedings and hospital reports, that great confusion exists in the medical mind to-day in regard to it. Dr. Byrnes's case, discussed in the New York Obstetrical Society during the present year, was taken as an illustration. In speaking of such cases, the great tendency to relapses in chronic pelvic inflammation was illustrated by two cases, in which pus-tubes were found five and seven years after attacks of peritonitis, and when it was supposed the patients were entirely restored to health. Upon the subject of treatment the writer admitted that by non-surgical therapeutic measures large intraperitoneal exudations are often absorbed, and even some tubal and ovarian inflammations entirely disappear, and recovery seems complete. But this is the exception, and by no means the rule. For the radical cure of chronic pelvic inflammation, non-surgical treatment fails in a majority of cases. A great many women, suffering to a moderate degree, continue to do so in spite of the best directed non-surgical measures, and perhaps wisely elect not to undergo operation.

As a rule, the only radical and permanent relief is afforded by removal of the diseased appendages. The treatment of pus collections, of course, requires abdominal section.

The Motive and Method of Pelvic Surgery.—DR. JOSEPH PRICE, of Philadelphia, followed with a paper on the above subject, in which he said pelvic surgery must be considered apart from abdominal surgery. It is distinct from it, both in the nature of the lesions dealt with, in the difficulties it presents, and in the complications and embarrassments to routine technique.

Nowhere as much as in pelvic surgery does the distinction between the general surgeon and the specialist in pelvic disease stand out so clearly. Pelvic adhesions in appendicitis, for instance, Mr. Treves would deal with by the knife. If this is feasible, why not put the knife to ovarian and tubal abscess, to all intestinal fixation by inflammatory processes and the like? The very suggestion of such method to the mind of the specialist, accustomed to deal with all the complexities of pelvic surgery, is fraught with evil, and this mere suggestion only makes it clear that general surgeons, in so far as they are entirely wedded to the knife in removing disease, fall short of the demonstrated harmfulness of its application in pelvic work.

Relative to electricity, Dr. Price said that electricians yet talk learnedly of the undetermined place of electricity in the treatment of ovarian cysts, but tar-water and tractors have gone to their long rest. The time must yet come when the claims made for electricity as a universal panacea must be exploded, and its real, limited, and narrow horizon of usefulness be well defined. The pernicious effect of so-called cures of reported complicated cases, adhesions, inflammations, and the like, by men without training, who look only at the ampèremeter while they adjust a clay pad or introduce a galvanic sound, is not to be over-estimated. He had repeatedly shown, by exhibited specimens, the fallacy of the claim of exact diagnosis made by these men, and the arguments are irrefutable. He believed that the only position assumed by the electricians that has the slightest foundation in fact, is that electricity will sometimes control hemorrhage and relieve pain. That it cures either is not proven.

In dealing with adhesions the first point to be sought after is to find a crease or crevice, into which some progress can be made. In separating intestinal adhesions they should be broken as far from the bowel as possible. The further away, the less liable will they be to bleed, and the absence of hemorrhage is a great comfort in these cases. The strings of adhesions may be dealt with according to their size; it sometimes being best to remove them, at others there is no necessity for this. In doubtful cases their removal is the better surgery. All bowel adhesions should be carefully examined after their separation. By so doing, fecal fistulæ will often be avoided by the careful placing of an intestinal suture. It hence is apparent that no pelvic surgery should be attempted until the operator is competent to deal with intestinal wounds, even to resection and anastomosis. Once the adherent mass is removed, the ligature should be applied close up to the cornu uteri. The ligature should not be so heavy as to resist knotting, nor so light as to break easily. The ordinary surgical knot is the safest of all knots with which to tie the pedicle. It constricts more evenly and certainly, and will slip less readily. The leaving of sufficient button is of the greatest importance to prevent slipping of the ligature.

In the treatment of extra-uterine pregnancy his urgent advice is, to operate without delay when the symptoms point to the disease, with the assurance that delay will only complicate matters and sacrifice the life of the mother.

The field of pelvic surgery, said Dr. Price, is not one of experiment or palliation; that it strives in all cases to remove the offending body in order to conserve the rest of the economy; that its tenets are founded on philosophy and fact, not fiction; and that its worth lies in its proven results. The surgery that plucks out the eye, or casts aside the limb to save the eye, or the limb, or the life, is greater, better, and wiser than a sentiment that preserves a shell to enclose a ruin.

AFTERNOON SESSION.

Suprapubic Cystotomy in a Case of Enlarged Prostate.—DR. W. H. H. COBB, of Goldsborough, N. C., read a paper on this subject. The patient, a farmer, married, aged forty-nine, rheumatic diathesis, dated his troubles back to 1881. While attending to the duties of register of deeds, he carelessly allowed over-distention of his bladder, and had suffered more or less since that time. In 1882 he had an attack of nephritic colic and passed a small calculus, similar in size and shape to a grain of wheat. On three different occasions he passed dark, gritty deposits. In 1883 he suffered much inconvenience and some pain in urinating. In 1887 he passed a dark, gristly, bloody substance about the size of a corn-pea, accompanied by much pain and bloody urine. For the

past three years he has suffered much with cystitis in a very aggravated form, with great pain and difficulty in defecation, urine containing much blood, pus, and mucus. The patient's efforts to relieve his bladder and bowels were tormenting, and night after night was spent in walking over his premises, with groanings so severe as to disturb his neighbors. The patient consulted Dr. Cobb, June 15th last, and from the history of the case he suspected vesical calculus, but failed, upon examination with sound, to detect any stone. A digital examination, however, per rectum, disclosed the right lobe of prostate greatly enlarged, rough, indurated, exceedingly tender and sensitive. After consultation by letter with Hunter McGuire, he decided upon suprapubic cystotomy as the only hope of permanent relief, which was done after the method of Dr. McGuire, on June 23d. At the expiration of two months (August 23d) he found the prostate perfectly normal, with no symptoms of cystitis, and withdrew the plug, allowing the fistula to unite, which it did in about ten days. His patient performs the acts of urination and defecation without the slightest trouble, and expresses himself as entirely relieved, and is at present following his usual vocation.

Inflammation in and about the Head of the Colon.—Dr. L. S. McMurtry, of Louisville, read a paper on this subject. He said the teachings to be found in systematic treatises on surgery and practical medicine, upon inflammation and its results in and about the caput coli, are not only worthless but positively misleading. This is true not only as to pathology and treatment, but even as to the anatomy and relations of the cæcum and its appendix.

It is well known that inflammatory changes in the vermiform appendix are in almost every case the origin and seat of the inflammatory diseases about the caput coli. Inflammation of the cæcum is very rare, yet the testimony of surgeons and pathologists is abundant that, in a certain proportion of cases cæcitis, with perforation, occurs without involvement of the appendix. Regnier, in 1886, operated in a case presenting symptoms of intestinal obstruction with peritonitis, doing an abdominal section. At the autopsy cæcitis, with perforation, was discovered. In 1888 the speaker operated in a case of perforative cæcitis and sutured two perforations in the cæcum. His patient recovered and was present in the Surgical Section of the American Medical Association, in May of that year.

Fecal impaction has been mentioned by surgical writers as a cause of inflammation about the head of the colon. Pain over the cæcum, with a fecal mass perceptible on pressure often occurs, but rarely, if ever, associated with peritonitis. A few weeks since Dr. McMurtry saw a case, in conjunction with Dr. H. H. Grant, of Louisville, in which a localized peritonitis existed in the right iliac fossa, with a well-defined, firm tumor. Abdominal section was done, and instead of appendicitis, they found the disease to be cancer of the caput coli. Irrigation and drainage rescued the patient from the immediate danger begotten by active peritonitis. The patient was a woman of middle age, and the engrafted peritonitis presented the symptoms of an acute condition. Malignant disease of the cæcum has not, so far as the writer is aware, been mentioned by writers upon this subject as a probable condition in the diagnosis of deep-seated inflammations of the right iliac fossa.

The decision to operate should be determined more by the grade of the inflammation than by the time it has existed. When a diagnosis has been made, and three days have elapsed without subsidence of pulse and temperature, operation should be done.

Dr. McMurtry submitted the following conclusions: 1. Inflammation about the caput coli is, as a rule, inflammation of the appendix. 2. A certain proportion of cases will recover spontaneously by resolution. With these recurrence of the disease is common. 3. In the larger proportion the disease will endanger life, and may at any moment assume a condition practically hopeless. 4. Early operative interference involves less danger than delay, and should be resorted to in all cases in which a high grade of inflammation is persistent. 5. The essentials of the operative technique are brief anæsthesia, quick and thorough work, removal of the appendix, irrigation, and drainage. The lateral incision is preferable to the median.

Evening Session.

The Causes of Ill-Health in American Girls, and the Importance of Female Hygiene, was the subject of an address delivered by President Engelmann. He showed that the health of the American girl is threatened and impaired by causes more or less avoidable, as they are due to our methods of life, our methods of training and education; that the physique of this girl, most favorably situated amid auspicious possibilities, is imperfect; her brain overworked, her nerve-power exhausted, her function impaired, and reproduction endangered, all by reason of the susceptibility of her peculiar organization, and the increased impressionability of the sensitive system during the years of development, in which it is subjected to the most severe strain.

The remedy is attention to woman's peculiar organization and the cyclical waves of her dominant function; or, in other words, harmonious development and occupation of nerve and muscle; diminished brain-work and nerve-stimulation, with increased and co-ordinate physical exercise; increased protection and diminished compression of dress; self-knowledge and individual care during periods of heightened susceptibility. Changes are necessary in custom and fashion, in methods of labor and education. A harmonious co-education of mind and body should be approximated, with coincident maintenance of proper hygienic conditions.

Dr. Engelmann closed with a plea for the self-care of the American girl and her proper physiological instruction by the mother, which will mitigate or remove the initial cause of many of her ailments. Upon the mother he would impress that the perfect development of the female function, and the maintenance of this function, once developed, in a healthy condition, is essential to the perfect development of the girl and the perfect health of the woman; that self-care, a well-regulated female hygiene, is the foundation of her well-being.

Second Day. Wednesday, November 12th—Morning Session.

Indications for Operation in Ectopic Gestation.—Dr. C. A. L. Reed, of Cincinnati, O., read a paper on this subject. The paper starts out with the assumption that the only proper treatment of ectopic gestation is by laparotomy, or, more properly, colotomy. While the profession has become practically unanimous that this is the proper line of treatment, the indications for operation have been less definitely decided upon. This conviction is forced upon the observer not only by a study of the literature of the subject, but by encountering cases which have been advised against operation by their attending physicians until hemorrhage within the pelvis has threatened a fatality, which is but too frequently realized. The most legitimate excuse for this dilatory practice is to be found in the confusion which has arisen with regard to the supposed uniform causal relationship of ruptured ectopic gestation to pelvic hæmatocele, and the division of the latter into "primary" and "secondary" rupture. These terms are unfortunate, and, as used in this connection, may be entirely arbitrary. Primary rupture is made to mean rupture beneath the peritoneum, instead of first rupture, as the etymology of the word would imply, while secondary rupture is made to mean rupture within the

peritoneum, instead of second rupture; whereas an intra-peritoneal rupture may be, and frequently is, a primary rupture, when spoken of with reference to the sequence of events in ectopic gestation There would be no serious confusion even here, if we were not also taught to leave extra-peritoneal hæmatoceles alone, to be taken care of by absorption, and if we did not add that, as these hæmatoceles are generally caused by ruptured ectopic gestation sacs, we are to relegate these cases also to the expectant plan of treatment. This conclusion is without warrant, and is responsible for hundreds of deaths annually from this one cause.

The treatment of ectopic gestation premises the diagnosis of this condition. This is obviously difficult, and in the majority of instances cannot be arrived at at all, or, if at all, only presumptively; but in all these cases conditions can be found in the pelvis, which, if not conclusive of extra-uterine pregnancy, yet constitute conclusive indications for exploratory operation. The presumption of ectopic pregnancy can be arrived at before rupture chiefly by a history of previous sterility, by a previous amenorrhœa, followed after a few weeks by irregular hemorrhage, by increased tumefaction to either side or back of the uterus, and by the existence of false decidua within the uterus. The latter fact may be safely determined by the judicious use of the Emmet curette forceps. The diagnosis after rupture is essentially the diagnosis of internal hemorrhage. Time wasted either to determine the cause of that hemorrhage, or to find out if it be primary or secondary, is criminal. The thing to do is to cut down and operate. The position has been taken that time should be taken for the patient to rally from the shock. One of Dr. Reed's own cases died simply because he waited twelve hours for reaction—a lesson which taught him the fallacy of the old teaching, and which has since saved lives at his hands. The best way to overcome shock from internal hemorrhage is to stimulate the patient by giving ether, stop the drain by ligating the bleeding vessels, and rouse the nervous system by washing out the belly with hot water.

Dr. Reed's conclusions are: 1. The only proper treatment of ectopic gestation is that by abdominal section. 2. The operation should be done in cases before rupture as soon as the condition can be presumptively diagnosed. 3. The operation should be done in cases after rupture as soon as the evidences of internal hemorrhage become apparent. 4. In cases in which the period of viability has already been reached without rupture, pregnancy should be allowed to advance to term before operation, but only under the closest possible vigilance. 5. In all cases the appendages from both sides should be removed, providing the condition of the patient will permit of the extension of the operation.

The Local and General Treatment of Gangrenous Wounds and Diseases.—Dr. Bedford Brown, of Alexandria, Va., followed with a paper on this subject. Many years ago, previous to the late war, Dr. Brown determined to institute a series of experiments to ascertain the capability of local and general treatment of all gangrenous wounds and diseases that came under his care, either for their prevention or arrest. The object was to find local agents possessing active properties as stimulants of vital action in the affected parts, also as means of disinfecting and deodorizing gangrenous sloughs, hastening their final separation, and for the establishment of a healthy basis for granulation. In cases coming under his care he found that the old deodorizer failed to accomplish these objects. He then employed a solution, almost saturated, of sulphate of zinc and dilute sulphuric acid as a local application, which seemed to meet all the requirements. The first case in which it was applied was according to the following formula:

℞. Zinci sulphatis..... ʒ j.
Aquæ..... Oj.
Acidi sulph dil..... ʒ ss.
M.

After the free application of hot water at 110° F., the solution was applied every three hours on bats of raw cotton. In the course of two days the sloughs separated rapidly, leaving a perfectly clean, healthy basis for granulation. This solution evidently possesses active antiseptic properties. It is an admirable deodorizer; it is clean and cleanses the parts effectually. In cases of great loss of sensation in the parts, weak circulation, reduction of vital action, and depressed vitality, he knows no agents better calculated to arouse nervous action and stagnant circulation, for as soon as the living basement is exposed it gives rise to intolerable pain. He has used this solution in all forms of gangrenous wounds and diseases, some limited, others extensive and associated with septicæmia, with benefit.

Dr. Brown cited the history of several cases of different varieties of gangrenous wounds and diseases treated by various methods.

Dr. Henry F. Campbell, of Augusta, Ga., made some impromptu remarks on "Vesico-vaginal Fistulæ."

The Treatment of General Septic Peritonitis, was the subject of a paper read by Dr. W. L. Robinson, of Danville, Va., in which he called attention to those cases which tended, by absence of pain and a seemingly improved condition after chill and fever, to mislead as to the necessity of operating, and instanced two cases of recent date, seen in consultation, in which septic peritonitis and secondary abscess existed in spite of the seemingly favorable condition of the patient. He says that often there is an utter disproportion between the pathological condition and the amount of pain and tenderness, a condition so often seen in puerperal peritonitis. He states that traumatic abdominal injuries, appendicitis, and pelvic inflammations are the chief causes of septic peritonitis, while of course any internal or external influence which produces suppuration may be the indirect cause.

He agrees with Dr. G. Frank Lydston, of Chicago, that in children falls, blows, etc., are the causes generally of peritonitis, and that because of the inability of children in directing attention to the seat of injury we often diagnose the disease too late. Dr. Robinson takes the stand that gonorrhœa is a frequent cause of septic peritonitis, and the reason why it did not always produce it was, that it did not invariably invade the uterus, and even when it entered the tubes the adhesions to the ovary rendered it self-limiting.

He holds that section, irrigation, and drainage is the treatment, and that where adhesions are extensive that salines should follow the operation, in order that the peristaltic action of the bowel would prevent reformation. Cases occur which, when seen by the surgeon, are too prostrated to undergo a complete operation, and the proper plan is to rapidly do what one can by section, irrigation, and drainage. Dr. Robinson instanced a case of recent date in which the patient was saved when seen only *in extremis*. He urges the surgeon to go prepared to resect, anastomose, etc., as complications may indicate; where conditions are diagnosed which will most likely terminate in septic peritonitis, such as recurring appendicitis, that preventive measures should be undertaken; and where great tympanites exists he would adopt Dr. Davis's mode of opening the bowel and flushing it out with hot water.

Dr. John D. S. Davis, of Birmingham, Ala., contributed a paper entitled "The Clinical History of the Episcystic Surgical Fistula, with Cases."

Afternoon Session.

Removal of Stone from Female Bladder through the Urethra, with Cases.—Dr. W. O. Roberts, of Louisville, read a paper on this subject. This paper was devoted simply to his individual experience in the extraction through the urethra of stone from the bladder of the female. The cases thus treated were six in number; the ages of the patients ranged from fifteen to fifty-six years. Four were married, but two only had borne children.

The stones were phosphatic in four cases, uric acid in one, and an incrusted fringed body in another. In one, a very hysterical patient, the stone had for its nucleus a piece of soft wood. In one the patient had a vesico-vaginal fistula which had been closed by an operation some months prior to the occurrence of the symptoms of stone. In another the bladder had been opened by a surgeon in doing an ovariotomy upon the patient, a year before the stone was discovered.

In four of the cases the stones were single, in one there were two, and in one nine. In this case the patient had passed at various times a number of small stones, from two to seven at a given micturition. These stones varied in size from that of a grain of wheat to a grain of coffee. In two years she had collected one hundred and eighty-four stones, a number not representing all she had passed.

The extraction was done in every case under chloroform, the patient being profoundly anæsthetized. The urethral dilatation was begun with forceps, and completed by means of the fingers; the little finger being first introduced, the ring-finger next, and finally the index-finger. The fingers were well oiled. In Case I. the stone was found to be almost an inch and a half in diameter. In Case II. the stone was found in the urethra, and proved to be a piece of soft wood heavily incrusted with urinary salts. In Case III. the stone was spherical, and had a diameter of about one-half inch. In Case IV. the stone was ovoid, its long diameter being an inch, the shorter three-fourths of an inch. In Case V. there were nine stones, the smallest measuring circumambientially two, and two and one-fourth inches; weight, eighty-four grains.

Wet Antiseptic Dressings in Injuries of the Hand, was the title of a paper presented by Dr. William Perrin Nicolson, of Atlanta, Ga. After dwelling upon the importance of the subject, both from the stand-point of the future earning capacity of the patient and the large amount of financial compensation demanded from corporations, he stated that for seven or eight years past he had looked after the surgery of several railroads and manufacturing establishments, and in that time had been called upon to treat more than three hundred hand injuries, representing all grades of injury, from slight contusion to complete destruction of the larger part of the hand. The especial point that was urged in the paper was the doctrine formulated by Verneuil—never to use a scalpel in a hand injury. The old teaching that, when a finger was crushed you should go far enough behind the injury to secure a sound flap and amputate, was pernicious in the extreme, and had cost thousands of fingers that would have been restored to usefulness. Only such parts as were actually destroyed and pulpified should be removed, and all the tissues to come away could be amputated with the scissors. Projecting pieces of bone could be removed with pliers until reduced to the level of the fleshy parts. In compound fractures the parts should be co-aptated as well as possible, and the line of separation be determined by nature, and under strict antiseptic dressings. Such a slough was harmless. Another point to which attention was forcibly called was the utilization of blood-clot in filling up ragged injuries, and by its substitution the restoration of lost parts. When a finger was crushed off, the end should be trimmed with scissors, and the clot utilized in building up a tissue over the bone. In reference to dressings, Dr. Nicolson said that he had tried almost all varieties, and had finally obtained the most satisfactory results from keeping the parts constantly bathed in a non-poisonous antiseptic solution.

In dealing with these wounds they were first cleansed as well as possible, and then bathed in a sublimate solution. Over all wounds a piece of aseptic rubber tissue or oiled silk was placed, then iodoform and sublimate gauze, and finally over all a covering of rubber tissue, into which, at some convenient point, a small opening was made. The patient was then given a bottle of antiseptic solution, to be carried in his pocket if moving about, and instructed to pour, at frequent intervals, enough into this opening to saturate the dressings. He uses almost exclusively listerine, combined with a small amount of carbolic acid, in the proportion of half an ounce of the former and half a drachm of the latter, in a six-ounce mixture. If there was much pain, a small amount of aqueous extract of opium was added. These dressings were not disturbed until the third day, when they were removed under strict antisepsis, to preserve the integrity of the blood-clot. Wet dressings were substituted at the end of about a week by the ordinary antiseptic dressings, kept moist by external covering of rubber tissue. Should sloughing occur, it is kept wet for a longer time with the antiseptic. Under this treatment pain was reduced to the minimum. Suppuration never occurred, and the separation of sloughs was facilitated by the warm moisture.

Uterine Moles and their Treatment, was the subject of a paper read by Dr. J. D. Wilson, of Sherman, Tex. In the few cases that had come under his observation, they had been more troublesome and elicited more anxiety than most writers indicate they should, and the hemorrhages in some of the cases were alarming; then too, there were some points noticed in his cases which he had failed to find described in text-books. All authorities seem agreed upon the etiological and pathological view generally taken of it, that it is a blighted or altered conception; the ovum having perished, its coverings or the placenta, if formed when this change takes place, becomes attached to and continues to receive nourishment through the uterine walls, and remains or becomes an organized product until it is thrown off; and this condition is attributed by some to the vitality retained in the villi of the chorion. He had never met with a case that was lying loose in the uterus, but all were more or less adherent to its walls, and most of them to the posterior wall. They had to be taken away piecemeal and the surface well curetted, washed out, and carbolic acid or Churchill's iodine applied to the surface. They all require after-treatment, because all except one case of hydatiform mole had endometritis and endocervicitis; two had severe cervical lacerations and erosions; most of them had a greater flow than usual at the subsequent menstrual periods until the inflammatory condition was relieved; in two cases the general health, while not robust, was fairly good; the others more or less delicate, none of them in perfect health; none had any history of a cancerous cachexia, nor of syphilitic taint; one was tuberculous. His experience had taught him to believe that if these cases do not receive treatment at a proper time there are two grave dangers to be apprehended, viz., hemorrhages, which, if not an immediate cause of death, are capable of leading indirectly to that end, and septic poisoning.

In the treatment, if the cervix is sufficiently dilated and hemorrhage troublesome, the mass should be promptly removed. If this cannot be done, a hot, antiseptic vaginal douche should be given, followed by a careful and efficient tampon, with the internal administration of ergot and anodynes if required, directing quiet, rest, and a simple diet. In from twelve to sixteen hours the tampon should be removed, and the foreign body extracted as completely as practicable; this will require a good stout pair of forceps. He had used the ordinary dressing-forceps and placental forceps for the purpose. An excellent instrument in some cases is Emmett's curette-forceps. The surface should be well curetted with a wire curette, the uterus thoroughly washed out with a hot solution of bichloride of mercury and Squibb's crude carbolic acid, or Churchill's tincture of iodine well applied to the surface. If much bleeding ensues—and this is not usual—the application of persulphate or perchloride of iron gives good results. The patient is put to bed and kept there as long as the indication in each special case may require; she is put upon a tonic treatment and hot vaginal antiseptic washes. In from three to five days the uterus may need curetting again and another intra-uterine douche;

then the application of iodine about twice a week, alternated occasionally, perhaps, with carbolic acid as long as may seem necessary, and the cure, if possible, completed of any uterine disease that may exist. The patient's general health is carefully looked after and her mind tranquillized.

THIRD DAY, THURSDAY, NOVEMBER 13TH—MORNING SESSION.

A Review of the Treatment of Varicocele, with Cases.—DR. G. FRANK LYDSTON, of Chicago, read a very elaborate and lengthy paper on this subject. He said, in discussing the various merits of operative procedures, it is unnecessary to take them up in detail. The *raison d'être* of many specially devised and named operations is apparent only to the operator. For practical purposes the various methods may be divided into (1) acupressure; (2) subcutaneous deligation; (3) open deligation; (4) deligation with resection of veins; (5) deligation with resection of scrotum; (6) resection of the scrotum.

The employment of acupressure, to Dr. Lydston's mind, was an evidence of a lack of faith in modern antiseptics. It reminded him of the Dutchman's method of cutting off his dog's tail, an inch at a time, so that it would not hurt him so much. Gradual obliteration of veins had all the dangers of immediate deligation in a marked degree, and had none of its advantages. The term acupressure covered practically all methods of gradual obliteration of the veins, of which Davat's operation is an illustration. Subcutaneous deligation is not essentially dangerous in skilful hands. Simple as the operation appears, however, accidents have occurred. The operation is done in the dark, and more tissue is included in the ligature than is necessary. Strangulation of tissue is not conducive of safety. Scrotal hæmatocele, phlebitis, septic infection, thrombosis, and embolism are possible. The vas deferens has been included in the ligature. He does not condemn the subcutaneous operation in suitable cases and in skilful hands, but he believes there are better and safer methods on the average. There is little choice between deligation without disturbance of the veins and deligation with resection of the veins, excepting the remotely greater danger of sepsis in the latter. Gould's method of division by cautery he believes to be the most dangerous operation yet devised. The dangers of the open method are in a less degree those of subcutaneous deligation. If open ligation be determined upon, the operation should be done as high up as possible in the straight portion of the veins, and a single ligature applied to the vein. Deligation with resection of the scrotum he considers to be the ideal operation in the majority of cases requiring surgical interference. His plan is as follows: An incision is made parallel with the spermatic cord just below the external ring. This incision should be about one inch in length. The cord is hooked out with an aneurism-needle, the veins separated and tied, the ligature cut through, and the cord dropped. Sutures and antiseptic dressings complete the operation. The scrotum is now amputated by the improved Henry operation. Dr. Lydston uses decalcified bone drainage-tube and juniperized silk ligatures and sutures. Resection of the scrotum he considers the simplest and safest operation for varicoceles of moderate size. In the more marked forms the affection invariably recurs to a greater or less extent. He does not, therefore, consider the so-called Henry operation a radical cure in the true sense of the word. The author reported a large number of cases operated upon by various methods, with the results and, as far as could be learned, the subsequent history of the patient. The author had noticed hydrocele as a result of subcutaneous deligation in two cases, one operated upon by himself, and the other by another surgeon. The doctor reported one very interesting case in which the scrotum was continually bathed in bloody perspiration and in which the seminal ejaculations were heavily tinged with blood.

Dr. Willis F. Westmoreland, of Atlanta, followed with some impromptu remarks on "Morbid Reflex Neuroses."

Silicate of Soda, Some New Methods of Use in Surgery.—DR. GEORGE A. BAXTER, of Chattanooga, read a paper on this subject, in which he said the jacket of baked silicate of soda which he would present to the Association possessed all the qualities to be found in the plaster, firmness and support, and weighs actually one pound and six ounces. It is neater in appearance and finish, can be perforated like leather for ventilation, which plaster cannot. It is even lighter than leather, without its costly process of construction, and has the same advantage over the woven-wire jacket, with the additional advantage over both these latter and all others of this class, that it can be constructed by any surgeon at any time or in any place. Dr. Baxter suspends his patient and puts roughly a plaster jacket around her, and cuts this as soon as it has hardened enough to retain its shape, thereby lessening materially the time of suspension, the most trying ordeal with this or the plaster, and not without its dangers when long continued; binds the cut edges together, where it has been cut down directly in front, with cords and then places a core of paper in the centre. This paper core is used for two reasons: (1) to lighten the cast and take as little plaster as possible, and (2) to dry it the more readily by heating the inside. This done, the plaster is poured around the core and inside the cast, which gives him a mould of the body in extension and counter-extension, exact in every respect. Around this is made the silicate jacket, after the manner of the plaster roller-bandage, weaving one-half inch metal strips in the meshes of the bandage at a distance of four inches apart around the whole cast, an inside lining of a knit shirt having been first placed over the cast. The whole is then placed over a coal-oil stove, and allowed to dry out, which it does in from one-half to two hours or less, especially if the cast has been previously dried. This process of heating not only dries the silicate but bakes it as well, and renders it impervious to the action of water or the perspiration, and gives it sufficient strength to allow of its being perforated for ventilation. It is now cut from the mould with a straight incision down the centre, two pieces of leather, to which button hooks or eyelets have been previously attached, sewed up and down the front on each side, then the whole can be laced up solid or loosened and taken off at will. The necessity of taking off a jacket or leaving it on during the whole course of treatment will, of course, depend upon the character of the disease or injury under treatment.

Surgery of the Gall-bladder was the subject of a paper contributed by DR. EDWIN RICKETTS, of Cincinnati, O., in which he said to Langenbach was due the credit of totally extirpating the gall-bladder, and to J. Marion Sims we owed a debt of gratitude for establishing the operation of cholecystotomy.

Dr. Ricketts reported four cases of gall stones:

CASE I.—Mrs. ——, aged thirty-eight, married, consulted him in 1880 for a tumor in her right side, in the region of the gall-bladder. Said she had passed by the bowel, following a severe attack of hepatic colic, a number of gall-stones. She was emaciated and suffered from what she claimed was neuralgia of the stomach. She was slightly jaundiced and bowels constipated. Upon examination of the abdomen the tumor was well marked and nodulated, above which was the liver surface, smooth. He made the diagnosis of gall-stone, and urged an operation. The patient's physician, however, urged the expectant plan of treatment, which was accepted by the patient. She then went to the country, and in less than three months had an attack of hepatic colic, followed by peritonitis, dying inside of three days.

CASE II.—Ellen ——, colored, aged thirty, consulted him for a markedly distended gall-bladder which made its appearance after a hard day's work over the wash-tub. She had been sick for ten days with fever, temperature reaching 103° F., rapid pulse, clayish stools, with occa-

sional attacks of hepatic colic, though not severe. He opened the gall-bladder, turning out one pint of fluid which consisted of bile, mucus, and pus, stitching the gall-bladder up against the peritoneum. After three days catarrhal plugs were washed out of the common duct through the abdominal incision, in which had been deposited a glass drainage-tube. The fistulous tract is still open, discharging periodically, but with no bad results to the patient.

CASE III.—A diagnosis of cancer of the liver was made by the attending physician. The gall-bladder was opened, and the stone turned out weighed one hundred and twenty-eight grains, and the common duct was filled with catarrhal deposits.

CASE IV.—After incising the gall-bladder there escaped first about one drachm of pus, after which Dr. Ricketts turned out twenty-eight stones. A diagnosis of cancer of the liver in this case was made by the attending physicians.

Dr. Hunter P. Cooper, of Atlanta, Ga., reported a case of "Fracture of the Femur Due to Fragility."

Dr. George H. Noble, of Atlanta, followed with an illustrative paper on "Procidentia Uteri."

AFTERNOON SESSION.

Rectal Medication was the subject of a paper read by DR. W. HAMPTON CALDWELL, of Lexington, Ky., in which he said that several years ago he was convinced of the utility and safety of rectal administration of medicine, and had ever since regarded it as a most important plan of treatment. Since we accept the theory of the local origin or manifestation of the majority of diseases, this idea of rectal administration of medicine was more easily accepted as scientific in its applications than at any time heretofore. The rectal suppository, consisting of cocoa butter incorporated with the various therapeutical agents, affords the most efficient and pleasant mode of administration in our possession. Rectal suppositories satisfy all requirements as a local or constitutional remedy; they are neat, convenient, and in almost every instance preferred by the patient to the administration of the same drug by the mouth. In the administration of anodynes, it is certainly a superior method of administration to all others, as the sensitive stomach is no longer a barrier or excuse in the administration of even the most disagreeable medical agent, for we well know in many instances that this organ is either tolerant to opiates or the patient has an invincible objection to taking them, the impossibilities of the rectal administration being thrown off is one great advantage over all other methods of administration. The effects of rectal medication embrace a wide range of actions, including anodyne, antiseptic, alterant, and astringent. In severe pain they certainly afford the best and safest source by which our patient's suffering can be relieved, as the action upon the rectal surface of a diffusible anodyne is quite rapid, and produces an effect as soon as when administered by the stomach. In all inflammatory or painful affections of the abdominal or pelvic organs, this plan of administration has succeeded better than all others with the author.

DR. THAD. A. REAMY, of Cincinnati, O., reported a case in which he removed a stone weighing 365 grains, by vaginal cystotomy, from the bladder of a child six years of age, with injury of the ureter. Operations done for closing the bladder were difficult, but ultimately successful. He exhibited the stone, and made some comments on the case.

He felt, after the stone was removed, that it would have been better to have made supra-pubic cystotomy. Had he known the size of the stone, he would have probably done that operation. But in view of the fact that it was partly encysted, that the bladder walls were much inflamed and thickened, also the fact that in the child the parietal peritoneum dips much lower down in front of the bladder than in the adult, it became a serious question whether this course would have been better than the one pursued.

It was not clear whether the ureter was damaged in the removal of the stone, or was exposed by the sloughing which occurred much later on. He was inclined to favor the former view; and that the discharge of urine into the tissues of the bladder wall, in the line of suture, was to no small degree responsible for some of the failures in closing the bladder. However, until the last operation the most critical examination failed to discover the ureter.

Though Parvin, Campbell, and others had turned an exposed ureter into the bladder, the speaker was not aware that it had heretofore been done in a subject so young. The vagina being so small, rendered the manipulation difficult in the extreme.

The Surgical Treatment of Empyema, was the title of a paper read by DR. JAMES A. GOGGANS, of Alexandria City, Ala. He said during the last eighteen months he had treated six cases of empyema which developed in the wake of pneumonia, all of which had made perfect recoveries. These patients varied in age from three to thirty-five years. Surgical treatment was the one which had been the most successfully employed. Spontaneous cures he said were rare—so rare that surgical interference was the rule. There were many methods of operating for the removal of pus from the pleural cavity, but they may be classified under two general headings: 1. The closed method, which consists in removing the pus by simple puncture with some kind of trocar or modern aspirator, and allowing the puncture to heal at once. 2. The open method, which consists in making an incision more or less free, with the introduction of some kind of drainage-tube to maintain the perfect evacuation of the fluid, and admit of medicated washings, and to promote free ingress and egress of air that has been passed through an antiseptic dressing. The surgical treatment then being an absolute necessity, we cannot over-estimate the importance of making the diagnosis certain by resorting to exploratory puncture with the hypodermic syringe. We can assure the patient and friends that no evil results can come from this procedure, and that the prognosis positively depends upon this means of settling the diagnosis.

Officers for 1891.—*President*—Dr. L. S. McMurtry, of Louisville, Ky.; *First Vice-President*—Dr. McF. Gaston, of Atlanta, Ga.; *Second Vice-President*—Dr. J. T. Wilson, of Sherman, Tex.; *Secretary*—Dr. W. E. B. Davis, of Birmingham, Ala.; *Treasurer*—Dr. Hardin P. Cochrane, of Birmingham, Ala.

Place of meeting, Richmond, Va., second Tuesday in November, 1891.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 4, 1890.

Benefactors.—On recommendation of the Council the following were elected Benefactors in recognition of their services to the Academy: D. Willis James, J. Pierpont Morgan, Edgar Starr, Charles J. Starr, William H. S. Wood, and Mrs. Eliza C. Farnham.

The Treasurer of the Board of Trustees, Dr. F. A. Castle, sent in his resignation of the office, other duties compelling him to take this step. The resignation was accepted, and a vote of thanks passed for his valuable services.

Nominations.—*President*, Dr. A. L. Loomis; *Vice-Presidents*, Drs. V. P. Gibney and E. L. Keyes; *Trustee*, Dr. F. A. Castle; *Treasurer of the Trustees*, Drs. A. S. Hunter, O. B. Douglas, and W. F. Cushman; *Committee on Admission*, Drs. D. Bryson Delavan, C. C. Rice; *Committee on Library*, Drs. John S. Warren, H. C. Coe, C. A. Powers, C. C. Rice, and C. L. Dana.

Amendments to the Constitution and By-Laws.—The amendments proposed by the Council were adopted.

Life Saving Methods in Still-Births.—DR. W. T.

Lusk read the scientific paper of the evening, which bore this title. The chief object in presenting the paper was to impress the need of persistent and intelligent application of known methods of procedure. These methods related to the clearing of the respiratory passages of mucus, etc., introducing air into the lungs by catheter, Sylvester's or Schultze's methods, aiding circulation by Schultze's method especially, and stimulating the respiratory centre by the means just mentioned, and also by the application alternately of warm and cold water. It was the manner of applying these well-known means which was all important. By their intelligent use, almost hopeless cases might finally be saved, while by their misuse life had sometimes been needlessly sacrificed.

The following was an illustrative case of successful efforts to save a still-birth: A few weeks ago he was called to the bedside of a primipara in labor. The child's head was in the pelvis, but for the past two hours had made no progress. Extraction of the head by the forceps was easily accomplished. The cord was tight around the neck. This he divided by the scissors, but when the child was extracted respiration had ceased; it was in a state of asphyxia. It was placed upon a table wrapped in warm cloths. The mucus was expelled from the posterior fauces. A No. 8 English catheter was passed into the trachea, and mucus was removed by suction. The quantity of the mucus in the bronchial tubes was large, and the catheter had to be introduced many times. Direct inflation was then practised. In ten minutes heart movements were observed, but they ceased again, and the steps already mentioned had to be repeated. But by perseverance in the treatment they at last observed a little color on the surface of the child. It was then immersed in warm water, lifted out, and cool water sprinkled on the epigastrium. Schultze's method was then practised, followed by Sylvester's. In employing the latter it was necessary to pull the tongue forward, and depress the base. It was not until nearly three hours of constant use of warm baths and cold sprinkling of the surface, alternate resort to Schultze's and Sylvester's methods that respiratory movements were finally established. The next day the child had cramps, but with constant medical attention these ceased after twenty-four hours. It was now in robust health and the joy of a family.

The means for exciting spontaneous respiratory movements should not be selected by divining rod methods, but by knowledge of physiological law. It was known that during the period of gestation the child remained in a state of apnœa, the respiratory function being performed by the placenta. As soon as the child was born in normal cases the thorax expanded, the diaphragm contracted, and pulmonary respiration was established. The premature establishment of pulmonary respiration while the child was still in the passages was followed by asphyxia and was the usual cause of still-births. Experiments on animals had shown that if, during uterine gestation, placental circulation were suspended the accumulation of certain materials in the blood was capable of exciting the respiratory centre in the medulla oblongata without the aid of peripheral stimuli, while the latter were capable of exciting the respiratory act before the internal stimuli had increased sufficiently to induce independent action.

At this point the author described the fœtal circulation by diagram.

The conditions which prevailed in asphyxia were somewhat different. When the child breathed in utero (and in nearly all cases of asphyxia after birth it had breathed in utero), we might say that the intra-uterine respiration was due either to tetanic contractions of the uterus (which was not uncommon at a time when ergot was given frequently before detachment of the placenta), to premature death of the mother, and, most common of all, to pressure upon the cord. Pressure upon the cord, cutting off the placental circulation, caused the child, as he had already stated, to breathe in utero. The amniotic fluid, meconium, epithelium, and mucus were drawn into the respiratory passages, first into the nose and throat, and, where the inspirations had been active, on down into the trachea and bronchi. There was at the same time increased tension upon the blood-vessels and right side of the heart. As no air reached the lungs the medulla lost its irritability and the respirations were suspended. At the time respirations were suspended the vessels and the heart were found enormously distended with blood. The lungs were also filled with blood, and when respiration had been well marked, there was pulmonary congestion, pleural ecchymoses, etc.

If the pressure on the cord were only temporary, the fœtal circulation would again resume its way and apnœa return.

In still-births the prognosis depended upon the degree of asphyxia. In milder cases the muscular tone was preserved, the head did not drop, the skin was dusky red or cyanotic, the conjunctivæ were congested, the umbilical vessels distended, reflex movements could be excited by irritation, etc. In these cases respiration often returned. In more advanced cases the head drooped, there was loss of muscular tone, the heart-beats were feeble and infrequent, the umbilical vessels nearly empty, the cutaneous circulation had disappeared, the surface was pale and cold, if respirations occurred they were very feeble, and were not associated with movements of the muscles of the face. The first sign of recovery was refilling of the cutaneous capillaries and regaining of muscular tonicity.

The indications in all cases were to clear out the air-passages, restore the irritability of the medulla, increase the force of the heart contractions, relieve the plethora of the heart and blood-channels, expand the thorax. Where muscular tonicity was yet present these conditions were easily fulfilled. But long-continued and careful resort to methods already suggested was called for in the second class of cases.

The author here demonstrated Schultze's method upon the infant cadaver. With the infant's back toward him, the operator placed his thumbs upon the head, the index fingers in the arm-pits, the hands diagonally across the back, the child's body hanging. Thus pulling up on the thoracic muscles, the upper ribs were drawn upward while the attachments of the abdominal muscles drew the lower ribs downward, the diaphragm descended, and in this way the cavity of the chest was expanded to the greatest degree, and inspiration was favored. Then by extending the hands horizontally, and giving a light turn forward and upward, bending the child forward, the abdominal viscera pushed up the diaphragm, the ribs were brought in close contact with one another, and the most efficient form of expiration was produced. There was, perhaps, no other way in which the mucosities in the lungs could be so efficiently expelled. In order to completely ventilate the lungs, the child was swung over between the hands a few turns before being laid away. But the greatest advantage was derived from the manner in which the congested heart cavities and vessels of the thorax were unloaded by these movements. Where there was deep asphyxia, all movements to restore the child should involve a minimum degree of disturbance, otherwise the heart would cease to act, and all signs of life become extinct. He had known this to occur in several cases. But there was no danger involved in aspirating the lungs through a hard rubber catheter.

Dr. W. M. Polk said he had little to add further than to indorse the points made in the paper. He thought it important to distinguish different degrees of asphyxia in treatment. For his own part, in asphyxia of the second degree, described in the paper, he always proceeded to use the catheter, feeling that the child had practically been drowned within the uterus or vagina. He seldom found it necessary to resort to any other procedure than this, except to practise Schultze's method in order to favor circulation. He had repeatedly been able to bring infants to life in which there was but a very slight heart-beat, by the use of insufflation through a rubber catheter.

In one instance of serious cerebral compression following the use of Tarnier's forceps, making it undesirable to save life, he was able by use of insufflation through a catheter to cause arterial color to alternate with venous hue during an hour and a half, the child in the meantime making no voluntary efforts at respiration.

Dr. H. J. Garrigues felt the importance of impressing upon every obstetrician the need of keeping up hope in trying to restore still-births. We should always retain hope as long as the heart continued to beat. And there were cases on record in which the accoucheur had restored life when the heart could neither be felt nor heard. He had himself had one case in which the first respiratory movement took place two hours and a half after birth. But he did not in that instance succeed in saving life permanently, the child living only about seven hours. This, however, would have been of great importance had the question of inheritance come up. According to the English common law, any sign of life whatever allowed property to be transmitted through the child.

In the first stage of asphyxia, he had many times resorted to Schultze's method successfully, and considered it a very rational procedure. If there were fracture of the collar bone, one of the other methods would be preferable. He placed in the category of irritants to the skin, faradic electricity. This he thought was useful, but did not approve of placing the pole over the phrenic nerve, believing it would not excite to action the diaphragm, and if it did penetrate that deeply it would be likely also to affect the pneumogastric and interfere with respiration. In catheterization, the best instrument was the English gum catheter, which could be moulded into any desired shape by dipping it into warm water.

Some Precautions.—Dr. R. A. Murray thought there was no method more powerful in relieving congestion of the heart and in aiding circulation than that of allowing some blood to escape on detaching the cord. But where the second degree of asphyxia was present, he proceeded at once to insufflation. The physician was apt not to clear the lungs of mucus as freely as he should, and was also likely to distend the child's lungs too much and too often. Twenty times a minute was often enough. The same precaution was necessary in the use of Sylvester's method. He also applied a stimulant to the rectum, say a small amount of whiskey, this part of the body being, as all knew, the last to come under the influence of anæsthetics and the first to recover sensation. The amount of whiskey employed should not be so great as to do injury if it were to enter the circulation. He believed many infants were killed by the improper use of cold and heat applied to the surface.

A New Form of Artificial Respiration.—Dr. A. S. Hunter thought the ideal method of artificial respiration was neither the Sylvester nor the Schultze. An objection to both was that the skin was exposed too long to the air, which depressed the vitality. He sat the child in warm water, from 100° to 110° F., placed his right hand on its back, the head falling between his thumb and finger; then with the left hand he raised the arms over the head, which extended and distended the thorax, the ribs being drawn up, the diaphragm being drawn down by the bodily weight. Having cleared the air-passages, the physician could bend forward and dilate the lungs by blowing into the mouth. In that position the air did not enter the stomach, for the head being thrown back, the cervical vertebræ pressed forward, closing the œsophagus while the larynx kept the passage to the lungs open. By this method he had obtained some remarkable results. It was very important to keep up the vital heat, especially if an hour or more were required in restoring life.

Asphyxia the Cause of Epilepsy and Idiocy.—Dr. A. Jacobi was prompted through Dr. Polk's remark that it was hardly desirable to save life in a certain case, to say that he knew of no greater danger for one's future than asphyxia at birth. A child's future depended a great deal upon the condition of its brain, and there was no organ in the baby's body so much exposed to damage in asphyxia as was its brain. The blood-vessels were very thin, hardly formed, so to speak; hemorrhages took place very easily, and were very likely to be large, for the further reason that the blood was very thin, containing at this age very little fibrin. If the little one could die at once, it would often be better for it, since to live might mean hematoma, meningitis, encephalitis, epilepsy, idiocy. He thought a large number of cases of epilepsy and idiocy in the families of the well-to-do had this origin. He therefore insisted that it was the obstetrician's duty, when he found the child on birth to be asphyxiated, to attend to it at once and leave the mother for a time to the nurse or assistant. The asphyxia should be cut as short as possible for the sake of the child's future. The subject dealt with by the paper was of extreme importance.

Dr. J. H. Dew said he had practised a method somewhat like Schultze's the past fifteen years. It was simpler, perhaps. The neck was held between the thumb and forefinger of the left hand, the head falling forward, the shoulders resting in the palm; then, with the right hand he seized the legs, bringing them up and pressing the body against the chest, which expelled mucus and favored expiration. The reverse action favored inhalation.

One Thousand Dollars for the Library.—Dr. E. L. Keyes presented a check for a thousand dollars to the library, with the condition that the name of the donor should not be made known. The gift was accepted with thanks.

Newspaper Notoriety.—Dr. A. Jacobi made a statement with regard to the notoriety which he was gaining the past few days in the daily papers, owing to the fact that he was to have received some of Koch's lymph. For some unaccountable reason the lymph had not come to hand, although it had been sent from Berlin, but the daily press had said a great deal more about the matter than he knew himself, and he took this opportunity for setting himself aright before his medical brethren.

The Aldermen and Garbage.—Dr. Janes called attention to the fact that the aldermen had recently passed an ordinance, requiring that hereafter receptacles for ashes and garbage be placed on the sidewalk, prior to removal by the city, and he requested the passage of a resolution declaring this to be a step backward in sanitary reform, and that a committee be appointed to wait on the Mayor, asking his veto. The resolution was adopted, and Drs. Jacobus, Crampton, and Hadden were appointed on the committee.

Correspondence.

MORE CONCERNING KOCH'S METHODS OF INOCULATION.

THE RESULTS OF THE TREATMENT OF INCIPIENT AND ADVANCED PHTHISIS, TUBERCULOUS GLANDS, AND TUBERCULOUS DISEASE OF BONES—THE INOCULATION AS A MEANS OF DIAGNOSIS—THE SCARCITY OF THE LYMPH—THE CROWDS OF MEDICAL MEN IN BERLIN.

[By the kindness of Dr. A. Rupp, of this city, we are enabled to publish the following letter, sent to him by Dr. C. Graefe, of Sandusky, O., who is now in Berlin.—Ed.]

Berlin, November 20, 1890.

Dear Doctor: Since the publication of Professor Koch's paper the throng of patients and medical men has been so constantly increasing that now the hospitals and clinics where Koch's specific is used are so crowded with those afflicted with tuberculosis that other patients have to give way, and the visiting doctors crowd the clinics to such an extent that students cannot get their seats. Koch himself, after announcing that he was compelled to make his discoveries known somewhat prematurely on account of the false impressions created by newspaper articles, has withdrawn into his laboratory to continue his

studies, leaving the preparation of the remedy in the hands of Drs. Pfuh and Libbertz, and the clinical experiments to Drs. von Bergmann, Fräntzel, Gerhardt, Cornet, and Levy. These gentlemen are the only ones who at present have any of the lymph, though it is said small quantities have been sent to Rome, Davos, Vienna, and London. Professor Koch, when he announced in his paper that small quantities could be obtained by physicians, probably had no idea of what the demand would be, for none can be obtained now, and the prospect for all, except large institutions, is very poor, as the present demands would take up the product of months with the present facilities and at the rate it is being prepared.

There is considerable speculation as to what the brownish liquid, smelling of carbolic acid, really is, and it has been thought to be toxalbumin, cyanide of gold or silver, a culture of the bacillus, or a ferment produced by such culture. It certainly takes some time to make it, will keep if kept corked in concentrated solution, turns white by the addition of pure alcohol, will bear a certain amount of heating, and in the diluted solution spoils by the formation of bacteria in it. It is diluted with boiled sterilized water, or a one per cent. solution of carbolic acid before using, and is usually injected between the scapulæ. Professor Koch has invented a new syringe, composed of the usual needle and glass cylinder, but the piston is replaced by a rubber ball, which, being squeezed, forces the liquid out by the pressure of the air. He recommends that the cylinder be washed in alcohol after each injection, and the advantages are that it is so easily taken to pieces that it can readily be sterilized and cleaned, so avoiding the formation of abscesses.

Having seen quite a large series of cases and the records of others, I can testify to the results of the application of the remedy as given by Koch. Where there is tuberculosis, in from four to six hours there is a rise of temperature, reaching, in some of the cases at Professor Bergmann's clinic, the height of 40.9 C., frequently accompanied by a chill, and sometimes by delirium. This gradually falls in from twenty-four to thirty-six hours, and the affected parts are congested, sore, and in lupus there is a serous exudation which dries into crusts. Sometimes the appearance becomes almost erysipelatous, and there is some necrosis of the skin, though usually the small tubercular spots are gone when the crusts come off, leaving a comparatively smooth surface. Professor Fräntzel reports, in four cases of advanced tuberculosis of the lungs, that there was the usual rise of temperature after the injection, but otherwise the cases ran the usual course, and the post-mortems revealed nothing special, except thick, slimy masses in the cavities.

The second series of eight cases were in the first stages, with induration of the apices of the lungs, and showed bacilli upon examination of the sputum. The patients were treated daily for from fifteen to fifty-six days, had the usual fever after the injections, but the night-sweats left them, the cough grew less, and they gained in weight, while bacilli could not be detected in the sputum after a time. Dr. Levy has been using the lymph since September 22d, on lupus and bone troubles, and Drs. Koehler and Westphal report a large series of surgical cases where they have used the remedy. I have seen about twenty cases of lupus during the past week, some of which have not been published. I to day saw a case of lupus, at Dr. Lazzar's clinic, where a carcinoma had formed in the scar, and the lupus was affected in the usual manner (infiltration, exudation of serum, etc.), while the cancerous portion was not affected. Professor von Bergmann showed a similar case last week, and in two cases where there was some doubt as to the diagnosis of a tumor of the cheek and a laryngeal trouble, there was no reaction, and the tumor was probably syphilitic and the laryngeal trouble cancerous.

Drs. Koehler and Westphal made the injection in four cases of ordinary scars after burns, cuts, and ulcers, and there was no reaction in these cases. Professor von Bergmann did the same with a boy with scrofulous glands of long standing, and there was no reaction, while in four cases of the same trouble there was a decided reaction and the treatment was continued.

The fever usually gradually decreases after the first three or four injections, and after a varying time tolerance is established, which is considered as the sign that the tubercles are destroyed. But the cases have not been under observation long enough to show that after a short time the reaction will not take place again. In Professor Bergmann's cases of bone trouble, abscesses, zonitis, coxitis, etc., the febrile reaction is accompanied with much pain in the affected parts and joints, which disappears more or less with the fever; and he will wait until the cases do not react after the injection before applying the usual plaster, fixation splints, etc.

The whole process is still in the experimental stage, and time alone will prove its true value. Koch is very modest in his claims for the remedy, and the most exaggerated reports of the cures effected by it fill the newspapers. As there is no lymph to be had, the process of its manufacture a secret, and the method of application so simple, it will scarcely pay to come to Berlin for the present, and many who came have gone away.

There are a number of Americans on the ground, and they are not the least active and interested of the visitors.

OUR PARIS LETTER.

(From a Special Correspondent.)

KOCH'S CONSUMPTION CURE IN FRANCE—INOCULATIONS MADE BY DR. SCHAFIER—PROFESSOR RICHET'S EXPERIMENTS ON THE PROPHYLAXIS OF TUBERCULOSIS—THE FRENCH REASONS FOR THE DEPOPULATION OF FRANCE.

PARIS, November 29, 1890.

IN Paris, as elsewhere, the subject that absorbs the interest both of the profession and the laity is Koch's alleged discovery of a "consumption-cure." The lay journals of all shades of opinion vie with each other in treating their readers to more or less sensational details of, and speculations on, the new treatment.

Much curiosity is, of course, manifested in the probable composition of the famous "lymph." The *Bulletin Médical* opines that the difficulty of its fabrication in adequate quantities points to the toxines secreted by the bacillus as its source, some other agent being added to insure stability. The general attitude of the people who proudly claim as their brothers Pasteur, Villemin, and Bouchard, is one of hopeful expectancy, untainted by any feeling of international jealousy. The fact that the deaths from phthisis pulmonalis alone in Paris average two hundred a week, naturally disposes us to welcome any cure for this fell disease, irrespective of the nationality of the happy discoverer.

Yesterday, at the St. Louis Hospital, Dr. Schafier, who has just brought from Berlin two small bottles of Koch's lymph, inoculated, for the first time in Paris, five patients (2 cases of tuberculosis of thigh, 2 of elbow, and 1 of foot), and this morning he was to further inoculate several cases of lupus. Professor Cornil has received two phials of lymph, each containing two grammes.

The experiments of Professor Ch. Richet on the prophylaxis of tuberculosis—experiments the results of which were communicated on the 15th instant to the Société de Biologie—are interesting at the present juncture. Having previously proved that the intraperitoneal transfusion of dog's blood into rabbits prerendered, experimentally, tuberculous, retards, without arresting, the evolution of tuberculosis, he now announces that, in collaboration with M. Héricourt, he has succeeded in rendering rabbits refractory to the invasion of the bacillus.

In April last he vaccinated 4 rabbits with a culture of tuberculous virus, attenuated by heat. He then inoculated them, together with 20 normal rabbits, with a very

virulent culture. Sixteen of the 20 normal rabbits died, while of the 4 vaccinated animals 3 are still alive and well, and 1 succumbed to spinal tuberculosis. Pursuing their researches in the same promising direction, MM. Richet and Héricourt, having inoculated a dog with 50 c.c. of extremely virulent bacillus culture, injected into the peritoneal cavity of 3 rabbits 150 c.c. of the dog's blood. (The dog seemed to suffer but little inconvenience from the inoculation; after being sacrificed the only morbid appearances detected were the presence of a few bacilli in the spleen). These 3 rabbits, subsequently inoculated with tuberculous virus, are still living, and have increased in weight, while of 3 "witness" rabbits, inoculated without having received any of the dog's blood, 2 died of tuberculosis, and 1 is in a dying condition. The value of these experiments is, unfortunately, considerably diminished by the fact that the cultures employed were derived not from man, but from birds.

Closely allied to the question of tuberculosis as a cause of high mortality in this country is that of the so-called "depopulation of France." That the population of France increases in but disappointing proportions is a melancholy fact; but when it comes to explaining this phenomenon and devising means to counteract it, "doctors differ" considerably. Following MM. Lagneau, Javal, Le Fort, and Brouardel, M. Hardy (Acad. de Méd., 18th inst.) ascribes the infecundity of his compatriots to the following influences: Racial peculiarities; a high state of civilization; easy circumstances; immigration into towns.

EXPERIMENTS WITH KOCH'S LYMPH IN LONDON.

Our London correspondent writes: The cry of the profession at present is the same as that of the Parisians just before the Franco-German war, viz., *à Berlin.* Berlin is, indeed, just now the centre of medical interest and many medical men from this country have proceeded thither in hot haste (somewhat tempered, at the present moment, by the sudden severe frost) to learn further details of Dr. Koch's method than they can gather from the public prints. A few experimental injections have been already made in London. Next week two public demonstrations are to be given, of which I shall hope to give some account in my next communication.

THE CARE OF THE PRIVATE INSANE OF NEW YORK.

To the Editor of the Medical Record.

Sir: In an editorial of the Medical Record appears an article entitled "The Care of the Private Insane;" issue of November 29, 1890.

I think the editor gives a wrong impression to his readers; also does a great injustice to the Lunacy Commission of this State.

It would appear from reading this article that the Commission had made no provision for that class of private insane patients who cannot afford to pay the rates of the private asylums.

The order of the Lunacy Commission, passed September 2, 1890, states as follows, in substance, that under peculiarly afflictive circumstances the Commission will grant an order for such patient to be admitted to a State asylum. This is a wise provision, and the Commission ought certainly to have credit for making such provision.

They also suggest that the State take a hand in the private asylum business, by creating extra asylums for the care of this class of cases.

I consider that the State should have just as good a right to build and operate a railroad, a hotel, or a medical journal (for physicians who cannot afford to buy a medical newspaper), and enter into competition with private individuals and private corporations generally.

The managers of private asylums are as heavily taxed as any other private enterprise, and ought to have a chance to make a living, also to raise the standard of private asylums as high as possible.

The class of private insane who cannot afford to pay our rates will be taken care of by the Lunacy Commission, who have shown themselves equal to the occasion in every case. Respectfully,

R. C. F. Combes, M.D.

[The editorial in question was written advisedly, and our contributor has not given any facts to disprove our position. The present provision for the private insane in the State asylums amounts to nothing. We were speaking of that class of patients who cannot pay for the accommodations in private asylums, and who are practically debarred by the present law from paying the moderate rates in our State Asylums.—Ed.]

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 30 to December 6, 1890.

Swift, Eugene L., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, relieved from further duty and station at Fort McDowell, Ariz. Ter., and assigned to Fort Thomas, Ariz. Ter., where he is now on temporary duty. S. O. 282, par. 16, A. G. O., Washington, D. C., December 3, 1890.

Pilcher, James E., Captain and Assistant Surgeon, now on leave of absence. By direction of the Secretary of War, will report in person to the Commanding General, Division of the Atlantic, for temporary duty at Fort Columbus, New York Harbor, during the absence on leave of Captain William E. Hopkins, Assistant Surgeon. S. O. 278, par. 3, A. G. O., Washington, D. C., November 28, 1890.

Hopkins, William E., Captain and Assistant Surgeon. By direction of the Secretary of War, granted leave of absence for six months. S. O. 278, par. 2, A. G. O., Washington, D. C., November 28, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 6, 1890.

Atlee, L. W., Assistant Surgeon. Ordered to examination, preliminary to promotion.

Martin, H. M., Surgeon. Placed on Retired List, December 4, 1890.

Alfred, A. R., Assistant Surgeon. Ordered to the Naval Hospital, Norfolk, Va.

Whitfield, J. M., Assistant Surgeon. Detached from Hospital, Norfolk, and ordered to the Chicago.

McCormick, A. M. D., Assistant Surgeon. Detached from the Chicago and wait orders.

Keeney, J. F., Assistant Surgeon. Ordered to the Minnesota.

Harris, H. N. T., Assistant Surgeon. Detached from the Minnesota, and wait orders.

Non-pyæmic Abscesses of Liver.—Dr. Robert W. Johnson, of Baltimore, Md., writes: "Permit me to correct an error in your report of my paper on 'Surgical Treatment of Non-pyæmic Abscess of the Liver,' published in your edition of November 29, 1890, in which you say, I 'principally advocated aspiration in even the smallest abscesses, as opposed to incision.' On the contrary I advocated incision, in two stages, in non pyæmic hepatic abscess after the diagnosis has been made sure with the aspirator."

THE ABSORPTION OF IMMATURE CATARACT BY MANIPULATION CONJOINED WITH INSTILLATION.[1]

BY RICHARD KALISH, A.M., M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL AND TO THE TRANSFIGURATION CLINIC, NEW YORK.

IN a paper read before the Section on Ophthalmology of the New York Academy of Medicine, on March 17, 1890, I announced my discovery of the method of curing cataract without the use of the knife. Before that announcement was made the only method known was to wait until the cataract became ripe, which necessitated that the patients become blind, or nearly so, before anything could be done to relieve them, and even then from four to six per cent. of those operated upon proved unsuccessful, incurable blindness being the ultimate result. Nor is this all. I have this winter seen two cases which had been operated upon more than a year ago. "A perfect success," the surgeon said. For about six months the sight was fairly good, then the "second" operation, needling, was called for, and since this was done sight has been very much reduced and an inflamed eye, painful in the extreme, has resulted in each case. As these two so-called successful cases have terminated so badly, may we not assume that others, primarily successful, were secondarily the reverse? In light of this I deem it opportune to again call the attention of the profession to the unvarying and permanent success attending the employment of my plan of treatment in uncomplicated immature cataract.

In the paper above referred to I stated that a number of cases additional to the six therein reported had been successfully treated, but so recent had been this treatment that their histories would be withheld until a sufficient period of time had elapsed to thoroughly test the permanency of the cure.

Before reading my paper I will submit for your inspection these diagrams, showing the ophthalmoscopic pictures of some of these cases before the treatment was instituted and the appearances observed at different periods during the course of the treatment. These diagrams were made from ophthalmoscopic inspection, examination, and study by Miss F. Elkins, whose skill in this direction is conceded by ophthalmologists. In employing the ophthalmoscope the view giving the greatest extent of lenticular opacity was the one diagrammed, and where it was not possible to show truthfully in one diagram the extent of the lenticular opacity, a second one, at a specified angle, was made. The degree of illumination, distance of the ophthalmoscope from the observed eye, angle of incidence of the ophthalmoscope, and focal length of the lens employed were carefully noted, and at stated times under precisely similar conditions the subsequent diagrams were made. It is but fair to state that all of the preliminary drawings were invariably returned to me at the same time as the finished diagrams, and by no possible means could, or did, the artist have any way to refresh the memory as to the previous appearances of a given cataract.

I propose in this paper to report those cases treated prior to July 10, 1890. These cases are reported by numbers, and in the same order as in my private case-book.

CASE VII.—Vision in the right eye on September 2, 1889, was $\frac{20}{100}$, and with + 2 D. Sph. was $\frac{20}{50}$; November 15th, was $\frac{20}{100}$, and with + 2 D. Sph. was $\frac{20}{50}$. Left eye, September 2d, was $\frac{20}{200}$, unimproved; November 15th, was $\frac{20}{100}$, and with + 2^{50} D. Sph. was $\frac{20}{70}$. Reading, September 2d, was Jaeger 13, but only a few lines, unimproved by spectacles; November 15th, Jaeger 7, easily read with + 4 D. Sph. for the right, and 4^{50} D. Sph. for the left eye. Duration of the treatment, about eleven weeks.

CASE VIII.—Vision was, in both eyes, September 3, 1889, $\frac{20}{70}$, unimproved; November 16, $\frac{20}{50}$, and with + 3 D. Sph. was $\frac{20}{40}$. Read, September 3d, with + 2 D Sph., Jaeger 7, but very slowly. Read, November 16th, with + 3 D. Sph., Jaeger 5, easily and clearly, and puzzled out Jaeger 3. Only a slight opacity remaining, but personal matters required her presence at home. Duration of the treatment, ten and one-half weeks.

CASE IX.—Vision was, in the right eye, September 3, 1889, $\frac{20}{200}$, unimproved; December 7th, $\frac{20}{100}$, and with + 2 D. Sph. was $\frac{20}{50}$. Left eye, September 3, 1889, $\frac{20}{100}$, and with + 1 D. Sph. was $\frac{20}{70}$; December 7th, $\frac{20}{40}$, and with + 1^{50} D. Sph. was $\frac{20}{30}$. Read, September 3d, with right, Jaeger 13; December 7th, Jaeger 9, and with + 2^{50} D. Sph., Jaeger 6. Read, September 3d, with left, Jaeger 9; December 7th, Jaeger 7, and with + 3 D. Sph., Jaeger 5. Newspaper easily read. Duration of treatment, thirteen and one-half weeks.

CASE X.—Vision in both eyes was, September 9, 1889, $\frac{20}{200}$ plus, and a weak convex glass made the letters clearer. December 14, 1889, $\frac{20}{100}$, and with + 2 D. Sph. for the right, and + 2^{50} D. Sph. for the left, was $\frac{20}{30}$; September 9th, with + 2 D. Sph. read Jaeger 13 at varying distances; December 14th, with + 3 D. Sph. read Jaeger 6 easily, and by straining could make out Jaeger 2. Newspaper easily read. Duration of the treatment, about fourteen weeks.

CASE XI.—Vision was, in the right eye, on September 17, 1889, $\frac{20}{70}$, and with + 1 D. Sph. $\frac{20}{50}$; November 22d, $\frac{20}{50}$, with + 1^{50} D. Sph. was $\frac{20}{30}$. Left eye, on September 17, 1889, $\frac{20}{100}$, and with 2 D. Sph., $\frac{20}{70}$; November 22d, $\frac{20}{40}$, and with + 2 D. Sph. was $\frac{20}{30}$. Read, September 17th, Jaeger 8, and could puzzle out Jaeger 5; November 22d, read Jaeger 4 easily, and with + 3 D. Sph. read Jaeger 1. At the upper edge of the lens periphery is an opacity about double the size of a pin's-head, but every other part of the lens is clear, no trace of an opacity being discernible. In the left only a general haziness remains, irregular in outline, and with + 4 D. Sph. newspaper type can be plainly read. Duration of the treatment, about ten weeks.

CASE XII.—Vision in both eyes was, on November 11, 1889, $\frac{20}{100}$, and with + 1 D. Sph. letters were clearer. January 25, 1890, $\frac{20}{30}$, and with + 1^{50} D. Sph. was $\frac{20}{20}$ plus; November 11th, read Jaeger 10 with the right eye, and Jaeger 11 with the left; not benefited by glasses; January 25th with + 4 D. Sph. for the right, and + 3 D. Sph. for the left, read Jaeger 6 clearly, and could decipher Jaeger 2. Very marked diminution in the density of the cataracts. Duration of the treatment, about eleven weeks.

CASE XIII.—Vision was, in the right eye, on November 18, 1889, $\frac{20}{70}$ plus; left, $\frac{20}{40}$ minus, unimproved by any glass; January 25, 1890, $\frac{20}{50}$ in both eyes, and could puzzle out $\frac{20}{30}$; November 18th, with + 2 D. Sph. read Jaeger 9 with each eye separately, together read Jaeger 6.

[1] Read before the Medical Society of the County of New York, November 24, 1890.

January 25th, with + $2^{5.0}$ D. Sph. for the right, and + $3^{5.0}$ D. Sph. for the left eye, read Jaeger 5 easily, and could read a few lines of Jaeger 1. The cataracts have almost entirely disappeared, that which remains appearing to be more in the nature of a capsular thickening than cortical opacity. Duration of the treatment, about ten weeks.

CASE XIV.—Vision was, in the right eye, on November 18, 1889, $\frac{2.0}{100}$, unimproved; January 31, 1890, $\frac{2.0}{50}$ and a few letters of $\frac{2.0}{40}$. Left eye, on November 18th, $\frac{2.0}{100}$, slightly clearer with + 1 D. Sph.; January 31, 1890, $\frac{2.0}{10}$ and a few letters of $\frac{2.0}{50}$; November 18th, with + 2 D. Sph., read Jaeger 9 with the right, and Jaeger 10 with the left eye; January 31st, with + $2^{5.0}$ D. Sph. for each eye, read Jaeger 5 easily, and could read a few lines of Jaeger 2. Duration of the treatment, eleven weeks.

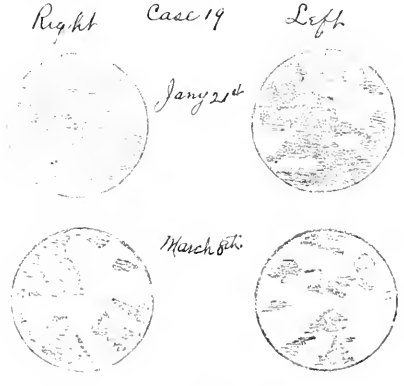
CASE XV.—Vision was, in the right eye, on November 18th, $\frac{2.0}{100}$, unimproved; January 30th, $\frac{2.0}{80}$. Left eye, on November 18th, $\frac{2.0}{200}$, unimproved; January 30, $\frac{2.0}{10}$. Read, on November 18th, with the right eye, Jaeger 10; January 30th, Jaeger 5 with + 3 D. Sph.; with the left, on November 18th, read Jaeger 12; January 30th, with + 3 D. Sph., read Jaeger 6, but not as clearly as with the right. Duration of the treatment, eleven weeks.

CASE XVI.—Vision was, in the right eye, on November 18, 1889, $\frac{2.0}{200}$, unimproved; January 30th $\frac{2.0}{80}$, unimproved. Left eye, on November 18th, $\frac{2.0}{200}$, and with + 1 D. Sph., $\frac{2.0}{100}$. January 30th, $\frac{2.0}{10}$, unimproved. Read. November 18th, with both eyes, Jaeger 10, and with + 2 D. Sph. it was clearer; January 30th, with + 3 D. Sph. read Jaeger 5, and could discern Jaeger 3. Duration of the treatment, about eleven weeks.

CASE XVII. will be described later on in connection with remarks on mature cataract.

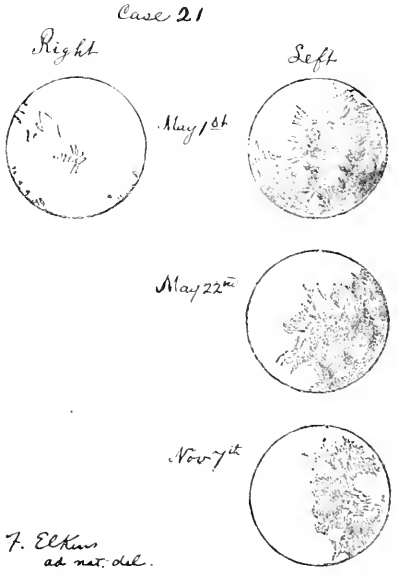
CASE XVIII.—Patient has always been so extremely myopic that it has been only by straining the eyes that she has recognized friends passing her; and even then it has been more by the attire or some peculiarity of gait than by sight. Vision on January 16, 1890, in both eyes, was about $\frac{3}{1.0}$. She could read Jaeger 8 at about two inches from her eyes. Treatment for three months, with intervals of rest intervening between the successive months. June 18th, vision was about $\frac{3}{200}$, and with — 8 D. Sph. she read Jaeger 6 at four inches. The cataracts are barely perceptible, and the sight the patient declares to be fully as good as before cataract was observed. There is a myopia equal to about 14 dioptries.

CASE XIX.—Vision was, in the right eye, on January 21st, $\frac{2.0}{10}$, unimproved; March 8th, $\frac{2.0}{50}$. Left eye, on January 21st, $\frac{2.0}{200}$, unimproved; March 8th, $\frac{2.0}{100}$. He could not read even Jaeger 13 because of the blurr over the letters. On March 8th, with + $2^{5.0}$ D. Sph., read Jaeger 6 slowly. Duration of the treatment, six weeks, when it was stopped, as illness in his family necessitated a trip to a warmer section of this country.



CASE XX.—The history of this patient dates from June 15, 1875, when her relatives were told that she had incipient cataract, her vision being, in the right eye, $\frac{2.0}{80}$, and in the left, $\frac{2.0}{20}$. I saw her on February 3, 1890, fifteen years later, and found the vision in her right eye to be reduced to $\frac{2.0}{200}$. Treatment was then instituted, and on April 23d her vision was $\frac{2.0}{50}$. In the left eye, February 3d, $\frac{2.0}{10}$, and on April 23d, $\frac{2.0}{50}$. Reading had not been entirely given up because of the sight remaining in the left eye, but reading for half an hour wearied both eyes so much that she was about ready to give up using her eyes for any near work. Two weeks after the commencement of the treatment she began to use her eyes moderately for reading, gradually lengthening the period of use, and at the end of a month was able to use her eyes for all purposes, unaware of any defect in her sight. Cataracts were markedly thinned, and left one quite so. Duration of the treatment, eleven weeks.

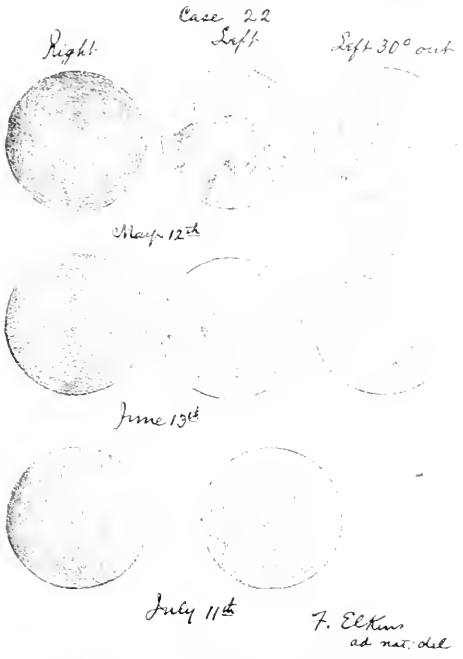
CASE XXI.—Myopia of about 6 dioptrics. Vision was, in the right eye, on May 1st, $\frac{5}{200}$, and with — 5 D. Sph. was $\frac{2.0}{10}$; June 7th, $\frac{6}{200}$, and with — 5 D. Sph. was $\frac{2.0}{40}$. Left eye, on May 1st, $\frac{5}{200}$, and with — 5 D. Sph. was $\frac{2.0}{100}$; June 7th, $\frac{3}{200}$, and with — 5 D. Sph. was $\frac{2.0}{100}$;



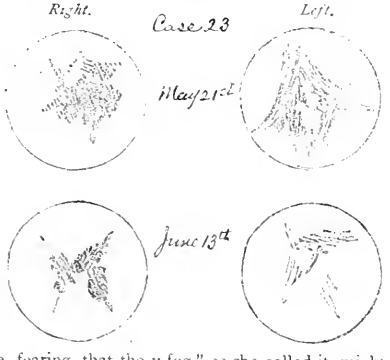
May 1st, read Jaeger 5 at six inches, but had no range of sight; June 7th, read Jaeger 1 at six inches, and with — 2 D. Sph. read Jaeger 5 at eleven to fourteen inches; May 1st, left eye could only read the letters on the thirty-feet line of the Snellen test-card at eight inches; June 7th, at the same distance, the letters of the twenty-feet line were read. The opacity of the right lens is entirely absorbed, not a vestige remains or is discoverable by prolonged and painstaking search. In the left eye considerable thinning of the opacity has taken place, and gross vision is much better. Duration of the treatment, about six and one-half weeks.

CASE XXII.—Vision was, in the right eye, on May 1st, Snellen test-card, the two-hundred-feet line at six inches; July 16th, at ten feet. Left eye, May 1st, $\frac{2.0}{200}$, unimproved; July 16th, $\frac{2.0}{100}$, unimproved. In the right eye practically no reading power. In the left, May 1st, Jaeger 13 with + 5 D. Sph., and on July 16th, with the same correction, read Jaeger 11. A reference to the diagrams will disclose that the cause for the defective reading power is found in the location of the opacity, which is directly behind the pupil, and the densest opacity fills up the pupil-

lary space. In addition thereto, the pupil itself is unusually small, and this interferes with the entrance of light and images. Sight for distant objects is greatly improved. Duration of the treatment was eleven weeks.

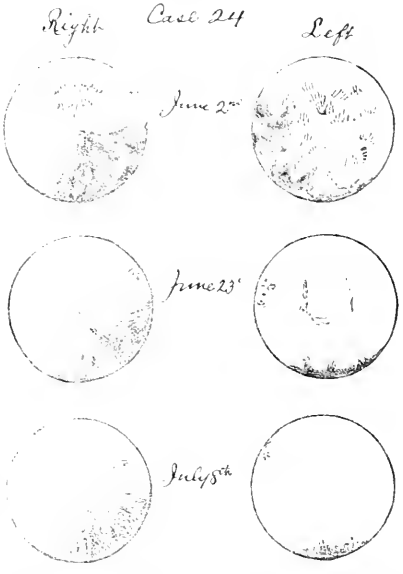


CASE XXIII.—Hyperopia of fully 5 dioptries. Vision was, in the right eye, on May 16th, $\frac{1}{200}$, and with + 2 D. Sph. was $\frac{2}{10}$; June 14, with + 2 D. Sph. was $\frac{2}{50}$. Left eye, on May 16th, $\frac{9}{200}$, and with + $2^{\frac{50}{0}}$ D. Sph. was $\frac{2}{10}$; June 14, with + $2^{\frac{50}{0}}$ D. Sph. was $\frac{2}{50}$. On May 16th, with her spectacles (+ 7 D. Sph.), read Jaeger 3 with both eyes; June 14, read Jaegar 1, using her spectacles. These cataracts were advanced beyond the incipient stage, and her sight was so blurred that she rarely went out



alone, fearing that the "fog," as she called it, might prevent her from seeing approaching persons. Under treatment her sight was so much improved that the "fog" has now disappeared, and by use of her spectacles everything is clearly seen. A reference to the picture will show how great has been this improvement. At the expiration of four weeks she went out of town for the heated term. From my observation in other cases, I would say that treatment for another month will bring about complete absorption.

CASE XXIV.—Vision was, in the right eye, on May 19th, $\frac{15}{200}$, but only at times; July 8th, $\frac{20}{200}$, and with + 0^{75} D. was $\frac{20}{100}$. Left eye, on May 19th, $\frac{20}{50}$, unimproved; July 8th, $\frac{20}{40}$, unimproved; May 19th, with right eye read Jaeger 13 slowly; July 8th, read Jaeger 9; with the left eye, May 19th, read Jaeger 10 at seven to thirteen inches, and made out Jaeger 9; with + 2^{25} D. Sph. read Jaeger 5 slowly, and with an effort; July 8th, with + 3 D. Sph. for both eyes, he read Jaeger 6 at eleven inches. The cataract in the right eye is reduced in size, changed somewhat in shape, and density greatly lessened. In the left eye only a faint line of lenticular opacity remains, situated at the lower periphery of the lens. The central opacity is completely absorbed, and further treatment, which will



be begun after January 1, 1891, will absorb the peripheral opacity. Sight for distant objects, using both eyes, is perfect. Duration of the treatment, seven weeks.

An analysis of these cases shows that the treatment has been invariably successful, the improvement being in direct proportion to the amount of lenticular opacity present at the outset of the treatment, that is, the less dense the opacity, the better the result; but all the cases have been benefited. Three cases were incipient in character, and in every one of them absorption of the central opacity was complete, at the periphery of the lens a slight opacity remaining, and this entirely out of the line of vision—two of these cases requiring prolonged search, with a lens of high power and a weak light illumination to reveal their presence. In one case the absorption is absolutely complete, the most rigid and exacting examination failing to show the existence of even the slightest opacity. In still another case four faint lines, like sectors, remain to mark the location of an immature cataract which had so seriously interfered with vision as to bring about a state of nervous exhaustion, alike alarming to her physician and friends. With the restoration of her sight a corresponding improvement in her general health has occurred. The remaining cases were more or less advanced in progress, but in every case useful vision has been permanently restored. In the consideration of the subject of the cure of cataract by absorption the first question which presents itself is this:

Will a case of mature cataract respond favorably to this treatment? With the intention of obtaining a reply to this query the following test was instituted:

CASE XVII.—Discovered suddenly that her left eye was blind, the reception on the cornea of the right eye of a fragment of stone causing her to close the eye. Vision in the right eye was $\frac{2}{30}$, and with + $0^{5.0}$ D. Sph. was $\frac{2}{20}$. In the left eye light perception only. By ophthalmoscopic examination the right eye was found to have a slight lenticular opacity at the periphery, and an hyperopia of one dioptris, and in the left eye a mature cataract with good light projection. The patient consenting to put herself under my care, treatment by manipulation, conjoined with instillation, was begun on January 4, 1890. At this time it was impossible for her to count the spread of fingers of the hand, even when held to intercept the light, and within a few inches of the eye. On February 26th, fingers were counted at a distance of six inches from the eye; on March 28th at ten inches; on April 30th at twenty inches, and on May 25th at twenty-four inches. On June 5th patient experienced a sudden numbness of the left side of the face, over the upper maxilla, which feeling spread upward, involving one-half of the head, and then passed downward as far as the knee on the same side of the body. This was followed by a sensation of pricking and then of sleepiness, "like the foot going to sleep," she described it. A little mental confusion was noticed, and a condition of semi-consciousness for a short time was experienced. On June 7th, two days later, I found her sensation and movements normal, and her sight reduced to counting fingers at about eighteen inches—a lessening of six inches; but on July 8th she again counted fingers at twenty-four inches. Treatment was then stopped for the summer. An examination made November 17th shows that fingers can be counted at twenty-six inches, a gain of two inches, and although there has been no treatment for four months she can discern the outlines of large objects. This case having shown such evidences of improvement, I feel that the time has not yet come to express a decided opinion, and that only after further experimentation will it be possible to answer this question.

The second question requiring a reply is this: How far advanced toward maturity can an immature cataract be and still be benefited by my plan of treatment? All my cases having been so markedly benefited, and the situation and extent of the opacity having so greatly varied in each case, I do not feel able to lay down any law or rule covering this point. In some cases with a decided opacity resorption seemed very active, and the clearing up of the opacity came about right speedily, while in others with less opacity the absorption took place much more slowly. Without formulating a decided opinion, I venture to make this statement, that it has seemed to me the more anterior the opacity, that is, the nearer the opacity was situated to the anterior capsule, the sooner did I observe evidence of the result of absorption, and the shorter was the period of treatment required. It is, however, incumbent upon me to say that in every case of immature cataract a marked diminution in the extent and density of the lenticular opacity was demonstrated by ophthalmoscopic examination, oblique illumination, and in those to whom the ability to read had been lost, reading power was always reacquired. The fact that every case was so much benefited does not allow me to set bounds at present to the application of the treatment.

A third and most important question is: Is the effect produced by my plan of treatment permanent? I do not hesitate to declare my firm conviction that the result produced is a permanent one. Not a single patient has had the slightest diminution in sight since the cessation of the treatment. I impress upon them the necessity of periodical reports as to conditions they may observe in their sight. In every case they have reported an improvement in sight, continuing after the stoppage of the treatment. This improvement, they say, becomes more apparent about two weeks subsequent to the treatment. I have had the opportunity, within the past fortnight, of subjecting to rigid examination two of the cases reported in my first paper, who were treated prior to March 1, 1889. In each case there was an improvement in vision, and an easily recognizable opacity, which was then present, can now barely be distinguished. This improvement in sight, observed in all my cases—non-progression of the opacity, but rather continuance of absorption of the cataractous process in a series of cases, some of them whose treatment was stopped more than nineteen months ago — establishes the permanently beneficial character of the result caused by my method of manipulation conjoined with instillation, and indicates the line of treatment to be adopted and faithfully carried out in curing immature, uncomplicated cataract.

In the history of these cases a curious circumstance has been noticed. This may be a concomitance only, but this I doubt. With only two exceptions these patients have for years been sufferers from aggravated forms of dyspepsia, and of the two exceptions one has suffered severely from time to time from attacks of indigestion with flatulency. The debilitating influence upon the system, from the absorption by the tissues of imperfectly digested food, which supplies an incomplete and abnormal nutriment to the body, brings about, as has often been proven, a serious disturbance of, and interference with, repair in the economy. Hence it is but natural to suppose that, under such conditions, the lens, in common with other parts, must not only suffer from lack of nourishment, but may also become changed in structure, and its functions interfered with, because of the reception by the organ of an altered and unnatural pabulum. We are therefore led to ask if dyspepsia may not, after all, often stand in a causative relation to the production of cataract, or, if it may not be a prominent agent in bringing this about. The existence of dyspepsia, in one form or another, in ninety-four to ninety-seven per cent. of my cases, seems to be good ground for the supposition that these troubles—dyspepsia and cataract—may often stand in the relation of cause and effect. Now, if subsequent investigation and observation shall confirm this theory, then for the general practitioner is opened up an extensive and far-reaching field of usefulness now unnoticed and unattended. By careful attention to, and judicious treatment of, the digestive troubles of his patients who have passed their fortieth year, he can, by checking a condition favorable to its development, materially and largely reduce the chance of the occurrence of cataract. My rule has been, and still is, to send these patients to their family physician, and I have noticed, as a constant effect, that as soon as appetite is improved, and faulty digestion made good, the cataracts show a marked tendency toward improvement in direct relation with the improvement in the digestive function.

Before announcing the conclusions arrived at I wish to state that in the MEDICAL RECORD of March 29, 1890, I have given full directions for the preparation of the solution employed, and for the manner and method of manipulation, for it is a peculiar manipulation, not a massage.

My conclusions are: 1. Further investigations are necessary before a decided opinion can be expressed as to the result of this treatment in mature cataract. 2. Immature, uncomplicated cataract can be benefited to the reacquisition of reading power, that is, to good, useful vision. 3. Incipient cataracts and those which have but passed into a state of immaturity can be entirely absorbed. 4. This being so, the sooner a cataract comes under treatment the better the result obtained. 5. The effect produced by my method of manipulation, conjoined with instillation, is permanent.

50 WEST THIRTY-SIXTH STREET.

Pretty Good for a Six Year Old.—Dr. A. H. S. writes: I circumcised a little fellow six years of age the other day, and when he recovered from the anæsthetic he remarked: "That is the meanest thing one fellow ever did to another."

SOME FACTS IN THE ETIOLOGY OF TUBERCULOSIS, EVIDENCED BY THIRTY AUTOPSIES AND EXPERIMENTS UPON ANIMALS.[1]

By H. P. LOOMIS, M.D.,
NEW YORK.

It is a well-known fact that tubercles are deposited in the bronchial glands of adults, subsidiary to deposits in the lungs, in about one fourth of all cases of phthisis. Some cases which show only a single small patch of tubercular change in the lungs present bronchial glands extensively diseased and often entirely caseous. It may also be added, in accordance with the report of cases as given below, that well-marked tuberculosis of the bronchial glands may exist where the lungs are perfectly normal, and no evidence of tuberculosis can be found elsewhere in the body. It was with the object of ascertaining the frequency of this latter class of cases that I commenced, eighteen months ago, a series of examinations of non-tubercular cases, and to render the conclusions as free from error as possible associated controlled experiments upon animals. In cases of phthisis in infancy and childhood, it is an equally well-established fact that an abundant deposit of tubercles in the bronchial glands is of great frequency, the disease in the glands being ofttimes as important as that in the lungs, and, in general, much more considerable. These evidences led Bollinger to carefully examine the bronchial glands of all children who died during the great epidemic of measles in Munich, in 1887. He found and proved that tuberculosis may be latent in a child in apparently perfect health, and also demonstrated the presence of tubercle bacilli in the swollen lymphatic glands at the root of the lungs and in the mediastinum in children who gave no evidence whatever of tuberculosis in the lungs or other parts of the body. It has further been demonstrated that in most cases of phthisis in children the disease has been preceded by a long-existent, but latent, glandular tuberculosis, the lymphatic glands in children being in a state of functional activity, and therefore by the slightest irritation becoming the seat of acute congestion. Papavoine mentions forty-nine children, of whom eleven were affected with tubercles in the bronchial glands without any in the lungs.

The following synopses of half a dozen cases presented during the last few years before the London and New York Pathological Societies are of interest here. Although they were not all confined to children, in all of them a tuberculosis of the bronchial glands preceded the general tubercular outbreak.

Cases from the London Pathological Society.—I. Caseous tubercle of the bronchial gland invading the lung; tubercular meningitis; general tuberculosis (vol. xxix., p. 322).

II. Acute tuberculosis; tubercular pleurisy and pericarditis, following caseous enlargement of the bronchial or mesenteric glands, in a child of eight months old (vol. xxvi., p. 246).

III. Caseation of bronchial glands; tubercular tumors of brain; miliary tuberculosis of lungs and kidney (vol. xxix., p. 11).

IV. Caseation and enlargement of several bronchial glands; one produced tuberculosis of mucous membrane of adjacent bronchus; severe pulmonary tuberculosis, in a child of nine months old (vol. xxx., p. 254).

V. Suppurating (caseous) tubercular bronchial gland opening into œsophagus and bronchus; tubercular ulcers of stomach and intestines; miliary tuberculosis of all organs (vol. xxxvi., p. 104).

Cases from the New York Pathological Society.—VI. General tuberculosis; enlarged bronchial glands, with ulceration into right bronchus (1888, p. 146).

VII. General tubercular meningitis; cerebral thrombosis or softening; enlarged bronchial glands, with ulceration into right bronchus, at seven months (1888, p. 147).

VIII Phosphorus poisoning; single enlarged bronchial gland, section of which showed tubercle bacilli (1889, p. 120).

Other Cases.—I. Old cheesy degeneration (tubercular) of bronchial glands; acute tubercular meningitis, few miliary tubercles in lungs, recent (Huguenin, in "Ziemssen's Cyclopædia").

II. Mass tubercular bronchial glands in a child of four which had produced symptoms of croup. At autopsy found to have softened and ruptured into trachea (Dr. Fuller's "Diseases of the Chest," p. 395, London).

III. Tubercular deposits in the bronchial glands and a single tubercle in the brain were the only lesions found in a case reported by Rilliet and Barthez.

From the foregoing it seems reasonable to question whether a similar glandular condition may not exist in adults, only becoming appreciable when a lowering of the vitality, or some unknown cause favoring the escape of the bacilli from the glands, sets up a general tuberculosis, then easily recognized. I have been unable to find any report or statement of observations which have as yet been made to settle this point. The only printed statistics which give an idea of the frequency of primary tuberculosis of the bronchial glands are made by Dr. Chambers in a report ("Decennium Pathologicum") of post-mortem examinations on five hundred and sixty-six tubercular patients at St. George's Hospital, during a period of ten years. He gives nine cases from among these as having glands and not the lungs involved; all were cases, however, in which the diagnosis was only made by gross appearance, and it is easily seen how this is liable to error. Professor Von Ziemssen, in his work on "Pulmonary Tuberculosis," when writing of latent tuberculosis in the glands of children, simply suggests the possible occurrence in adults. Zeigler, in his last work on "Pathological Anatomy," under the subject of "Phthisis," states that bronchial glands may be tuberculous throughout their entire extent and yet no changes at all be discovered in the lungs. How he reaches this conclusion he does not say. Cornil introduced into the trachea of guinea-pigs a few drops of tuberculous culture and observed submucous tubercular lesions with rapid generalization, and afterward demonstrated tubercle bacilli in the bronchial glands, thus showing that the bacilli may reach the bronchial glands directly through the tracheal mucous membrane. Before my attention was called especially to the bronchial glands I had made many autopsies on cases of acute pulmonary or acute general tuberculosis, and although it seemed undoubted that lesions must exist somewhere to show where the tubercle bacilli entered the body, multiplied, and gained headway before being able to produce a general infection, the spot was not ascertainable. For the last year I have examined carefully the bronchial glands in this class of cases and have been surprised to find in how many instances the glands were extensively involved and the lesion far advanced, and apparently antedating the general eruption. For instance, on March 4th of this year I made an autopsy on a young woman, twenty-six years of age, who had been in perfect health until four weeks before her death, when she was seized with fever and chills, which led to the diagnosis of malarial fever; one week later the diagnosis of general pulmonary tuberculosis was made. At the autopsy both lungs were found studded throughout their entire substance with small, gray, miliary tubercles; no old tubercular foci were found in the lungs, nor any other evidence of disease, except tuberculosis. No point of infection could be found, except one large bronchial gland, which presented the characteristic changes of an old tubercular process. At a meeting of the New York Pathological Society, on February 27th, Dr. Van Giesen presented an enlarged bronchial gland removed from a patient who had died of phosphorus poisoning. Sections of the gland showed it to be tubercular. No tubercles were found in any other part of the body.

It has been demonstrated that tubercle bacilli may be

[1] Read before The Society of the Alumni of Bellevue Hospital.

inhaled in respired air. The position of the bronchial glands and the arrangement of the lymphatics in the respiratory tracts render it easier for the inhaled tubercle bacilli to enter them than the lung parenchyma, for it is to be remembered that at the branching of the trachea between the right and left bronchi is a group of glands, from ten to fifteen in number, varying in size from a small pea to an olive, and that just beneath the mucous membrane of the lower portion of the trachea, and the mucous surface of all the bronchi is an immense net-work of lymphatic vessels running directly into the bronchial glands; also different lymphatics reach these glands from the lungs, the pleura, and adjoining parts. The blood-supply of the gland is from the bronchial arteries, and the blood is returned to the bronchial veins, and so to the right side of the heart. On the mucous surface of the trachea and larger bronchi the tubercle bacilli would be more liable to lodge, than to be carried down to the pulmonary alveoli. If the integrity of these mucous surfaces is weakened, as occurs during mild attacks of bronchial catarrh, the direct passage of the tubercle bacilli into the bronchial glands would be favored. The tubercle bacilli, having once gained entrance to the bronchial glands, would there find fit soil for development and a temperature most favorable to their growth. In the cases which I have examined the tubercular infection did not appear to have begun simultaneously in all the glands, nor to have advanced with the same rapidity in each gland. One or two abnormally large glands are probably found at the bifurcation of the trachea, which form an irregular, rounded, lobulated mass, measuring two, or even more inches in diameter. The other bronchial glands vary in size from a natural bulk to that of an egg, a few only or several may be affected.

Many of the glands affected will present a general tubercular lesion, being dense, firm, and scattered throughout with tubercular masses. These glands are often very much pigmented, and are generally surrounded by a dense capsule of connective tissue, firmly binding the gland to the surrounding parts. The natural thin involucrum of the gland always thickens as tuberculosis advances. This condition was especially noticed in the bronchial glands removed from the cases which I have collected and which were proven by inoculation experiments to have contained bacilli. Adhesions to the bronchial tubes are formed through the medium of an areolar tissue, which is at first loose in its texture, but becomes more dense. It would seem to be a conservative process limiting the tuberculosis and accounting for the fact that bacilli were present within the organism without producing any evil effects. Sometimes the glands become so infiltrated as to constitute a yellowish-white friable substance in which no vestige of the pristine texture remains discernible. Frequently in the glands are to be found encysted, cheesy, or calcareous masses, sometimes quite large, the cretaceous material being, as a rule, near the centre of the gland.

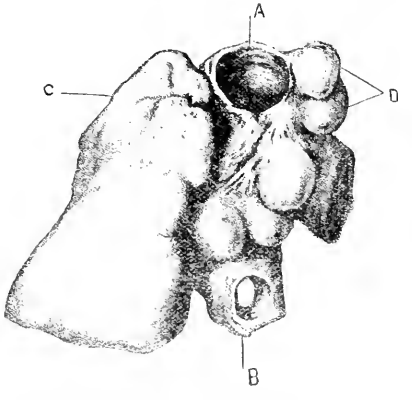


FIG. 1.—Enlarged Tubercular Bronchial Gland. *A*, trachea; *B*, right bronchus; *C*, enormously enlarged bronchial gland, proven by examination to be tubercular; *D*, collection of bronchial glands between right and left bronchus, slightly enlarged.

Fig. 1 is an accurate reproduction of a collection of enlarged bronchial glands removed from Case XXX. Six glands were removed, one of which was nearly as large as the one shown in the drawing. These were in

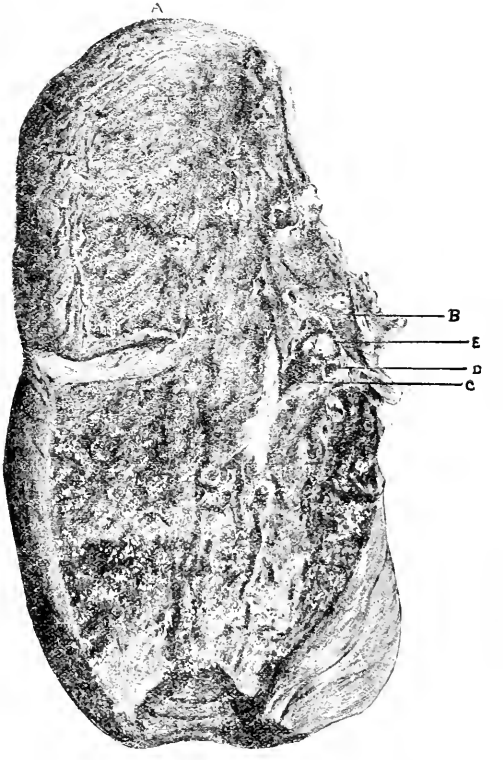

FIG. 2.—Photograph of a Normal Lung, showing Tubercles in an Enlarged Bronchial Gland. *A*, apex of lung; *B*, root of lung; *C*, enlarged bronchial gland above left bronchus; *D*, *E*, two tubercles in gland.

jected in the usual way into a healthy rabbit, which at the autopsy showed the characteristic lesions of a general tuberculosis, proving that the enlarged glands contained tubercle bacilli. The posterior part of gland *C* was cut into and presented the gross appearance of a chronic tubercular process, with caseation and fibroid changes.

It is possible, although hardly probable, that in the cases where the lungs were examined very carefully for the slightest trace of a recent or old tubercular process, the tubercle bacilli might have reached the glands after first having lodged in the pulmonary parenchymata, setting up so slight or so localized changes as to be overlooked, then to be carried by the lymphatics to the glands at the root of a lung. It seems much more probable that the bacilli reach the glands through the lymphatics of the mucous membrane, of the trachea, of the large bronchi, or even of the smaller one. Since the bronchial veins return the blood to the right heart, and so back to the lungs, may not the development of an acute pulmonary tuberculosis from infected bronchial glands be explained by the venous blood system taking up some elements from a softened, cheesy, lymphatic gland and

carrying this substance to the lungs? An exact reproduction is here given of the photograph of a lung removed from a person who died of an acute non-tubercular disease. Dr. T. M. Prudden kindly furnished me with the specimen. The lung was perfectly normal, and was laid open by a vertical incision from apex to base, and includes the structures at the root of the lung. At the root of the lung, just above a large bronchus, is seen an enlarged bronchial gland, 4 ctm. in length and 3 ctm. in width, pigmented, dense, and firm. In its upper part are seen two large tubercles, one the size of a small cherry, which on microscopical examination presented the characteristic appearances of a tubercular mass. The autopsy and microscopical examination of the case were conducted by Dr. T. M. Prudden, and no tubercular lesions were found, after careful examination, in any part of the body.

Here was unquestionably primary tuberculosis of the bronchial glands. How long the tubercle bacilli were in this gland it is impossible to say, as well as how long they would have remained there comparatively harmless. Analogous cases are found in encysted cheesy masses at the apex of the lungs, which remain long after physical signs and rational symptoms point to any change. How great the danger must be while the bacilli are present in the organism, no matter how apparently circumscribed they appear to be, anyone can see. The demonstration of the tubercle bacilli confined to the bronchial glands would explain the manner in which they might gain entrance into the lymph or blood-current, and so be carried to a point furnishing a fit soil for their development. And right here may be the explanation of tubercular joint disease and tubercular meningitis. Also, may not these experiments furnish an explanation of the development of pulmonary tuberculosis in persons with no hereditary physical tendencies, who, at the time of its development, are under the best hygienic conditions, in whom the tuberculosis seems to be excited by an acute, simple, bronchial catarrh, or by some other acute, non-tubercular, pulmonary disease?

It was with the hope of obtaining some facts which might throw light upon these questions that a series of autopsies was undertaken on persons who had died suddenly, either from accident or from acute non-tubercular disease.[1]

In all such cases a careful examination was made of each organ, especially the lungs, for evidences of old tubercular processes; if none were found, then the bronchial glands were removed, and placed in melted paraffine, so that the hot paraffine would destroy all putrefactive bacteria that might contaminate the surface of the glands, and would render them sterile until an animal could be inoculated with their substance. Within half an hour after removal the glands were taken from the hardened paraffine, washed with a bichloride solution, and reduced to a pulp in a sterilized crucible, to which a small amount of distilled water was added to render the fluid obtained from the glands thin enough to pass through the needle of a sterilized Koch syringe. About two cubic centimetres of the fluid which had been obtained from the pulverized bronchial glands were then injected into the right pleural cavity of a healthy rabbit. The rabbit was kept under the best hygienic surroundings, and if it did not die before the end of six weeks was killed by being bled to death. A careful record was kept of the autopsy of the rabbit, and of the microscopical examination of the organs. If the first rabbit at the autopsy showed evidence of tuberculosis, a second rabbit was inoculated, under antiseptic precautions, with material obtained from the first, to determine positively the character of the lesions found in the rabbits which were inoculated with the bronchial gland substance. Eleven rabbits died within twelve hours to six days, either from a faulty inoculation, too large a quantity of fluid being used, the animal being injured by the needle of the syringe, or possibly because the glands had undergone decomposition, the autopsy on the body from which they were removed having been made too late. From these cases no conclusions could be reached, and they are not included in the list of experiments.

The question might arise, in determining the presence of the tubercle bacilli in the bronchial gland, instead of inoculating animals with the material of the glands, why not cut sections of these glands and stain them for the tubercle bacilli? The reasons, to my mind, are two, viz., in the first place, the bacilli in the glands may be so few and scattered that it might necessitate a hundred sections being made to obtain, under the microscope, that portion of the gland containing the bacilli; and, secondly, in the appreciation of a small number of bacilli a personal factor comes in—one observer affirming their presence, while to another they are obscure. In answer to the objection that the material may have become contaminated before its inoculation into the animal, it may be stated that all the steps of the operations were conducted under the strictest antiseptic precautions, even to the removal of the glands from the dead body by sterilized instruments.

Eight out of the thirty persons on whom autopsies were made had in their bronchial glands active tubercle bacilli. None of the persons presented any evidence of old or recent tubercular process, yet the bacilli were within the bronchial glands, ready to enter the general lymphatic system of the lungs and set up a localized pulmonary tuberculosis, or by entering the general lymph or blood-current give rise to a general tuberculosis.

The following is a report of the cases upon whom autopsies were made, with the result of the inoculation experiments upon rabbits:

Case I.—An intoxicated woman was taken during the night to a police station and locked up in a cell. On the following morning she was found lying on the floor unconscious. Before medical aid could be summoned she died.

Autopsy, ten hours after death. The body was well nourished, and apparently in the prime of life. The kidneys were cirrhotic. There was slight thickening along the base of the aortic valve. No tubercular process, either old or recent, was found in any portion of the body.

One large and four small normal-looking bronchial glands were removed.

Inoculation Experiments and Results.—The glands were prepared in the ordinary way. Three c.c. of the fluid were injected into the right pleural cavity of a healthy rabbit. Forty-five days afterward the rabbit, much emaciated, was killed. Both lungs, liver, spleen, and kidneys were completely studded with small, gray, miliary tubercles. The mesenteric glands were similarly involved. Tubercle bacilli were found in a section cut from the liver and lung. A pure culture on potato was made from the rabbit.

The single enlarged bronchial gland removed from this woman, which measured one-half inch by one inch, had all the appearance of an old tubercular process. As the rest of the glands appeared normal, it seems probable that the infection of the rabbit came from this enlarged gland. This rabbit at the autopsy presented similar lesions to those found in rabbits inoculated with a pure culture of the tubercle bacilli.

Case II.—G. J——, aged thirty-two, a prize-fighter, who had come from California to give exhibitions in New York, was seized, upon his arrival here, with a chill, developed lobar pneumonia, and died on the seventh day of the disease.

Autopsy, made thirty-six hours after death. All the organs were found in a normal condition with the exception of the lower lobe of the left lung, which presented the ordinary appearance of the second stage of lobar pneumonia. There were no pleuritic adhesions, nor any

[1] My position as Curator of Bellevue Hospital, and the courtesy of the city coroners, enabled me to obtain autopsies on this class of cases.

evidence in any organ of the body of an old tubercular process. Four bronchial glands were removed, one of them being fully three times the normal size.

Experimental Inoculation and Results.—Immediately after removal 2 c.c. of the fluid obtained from the bronchial glands were injected into a healthy rabbit. Seven and a half weeks later the rabbit was killed. At the time of the inoculation the needle had pierced the diaphragm, and the injected material had entered the peritoneal cavity and infected the glandular system of the phrenic centre, resulting in a localized tuberculosis. On opening the abdomen a mass of three large grayish-white nodules, the largest measuring one inch and a half in diameter, was found on the anterior superior surface of the liver. On the under surface of the diaphragm, connected with these, were fifteen to twenty small cysts, filling the upper and right side of the abdominal cavity. In each cyst was a small cheesy mass. The large nodules were found, after careful dissection, to be enlarged glands of the phrenic centre, while the small ones were dilated mesenteric lymphatics. Eight small, white, round nodules were embedded in the right and left lobes of the liver. In these nodules tubercle bacilli were found by the Koch-Erlich method of staining. The rest of the organs were perfectly normal, with the single exception of the lower lobe of the right lung, which contained a small translucent nodule.

A second rabbit was inoculated in the right pleural cavity with two small nodules removed from the first rabbit. Ten weeks later this rabbit was killed, and in both lungs were found a few miliary nodules which on microscopical examination proved to be tubercular. All the other organs were normal.

A man of perfect health, and of extraordinary strength and physical vigor, is suddenly seized with an acute disease, and dies on the seventh day, and is found to have had tubercle bacilli in his bronchial glands, the presence of which was demonstrated not only in stained sections, but by the results of the inoculations of rabbits. It would seem that the amount of virus in the second rabbit was so small that the animal readily overcame the infection.

CASE III.—M. F——, aged thirty, was perfectly well until her confinement. After delivery she developed symptoms of puerperal septicæmia, and died on the ninth day.

Autopsy, made four and a half hours after death. All the organs were found in a normal condition, with the exception of the kidneys, which presented, under the microscope, moderate parenchymatous degeneration; and the uterus, which was enlarged, and contained a sloughy endometrium, with portions of the placenta still attached. The spleen was enlarged, soft, and pliable. Four slightly enlarged bronchial glands were removed.

Inoculation Experiments and Results.—A healthy rabbit was inoculated in the right pleural cavity with a syringeful of the fluid obtained from the crushed bronchial glands. The rabbit died at the end of five weeks. The right pleural cavity was covered with a dense fibrinous exudation, which compressed the lung, in whose lower lobe a small patch of consolidation was noted. The left pleural cavity contained some serum and fibrin at its lower part; the lung was normal. There were evidences of fibrinous pericarditis. The liver was studded with a number of small, white, translucent nodules, with cheesy contents. Microscopical examination of these nodules failed to reveal tubercle bacilli.

Five cubic centimetres of the fluid obtained from five of these nodules were injected into the pleural cavity of a healthy rabbit, which was killed at the end of nine weeks and found to be in a perfectly normal condition.

While the nodules found in the liver of the rabbit presented an appearance resembling tubercular nodules, the control experiment showed conclusively that they were non-tubercular.

CASE IV.—J. R——, aged forty, a street vender, while following his business pushed a cart before him about the streets. As he sat on the curb-stone with his cart in front of him, on the afternoon of May 17th last, a truck was driven against the cart, the handle of which struck him in the chest. He fell over and died almost instantly.

Autopsy, twenty-four hours after death. All the organs were normal. The man had died from fracture of the second, third, and fourth ribs, the vena cava being ruptured by the ragged edge of one of the ribs, filling the pericardial and pleural cavities with blood.

Five bronchial glands of normal appearance were removed.

Inoculation Experiments and Results.—A healthy rabbit was inoculated on May 19th, the glands having been kept over night in hardened paraffine. On July 18th the rabbit was killed, and all its organs were found in a normal condition.

This case proved, firstly, that the bronchial glands contained no tubercle bacilli, and, secondly, that the glands remained perfectly sterile for twenty-four hours in the paraffine.

CASE V.—J. E——, aged thirty, was admitted to Bellevue Hospital on May 27th, in the eighth month of pregnancy. She had been in perfect health until two weeks previous. At the time of admission she presented the symptoms of puerperal uræmia. Four days later labor was induced and a dead child delivered. On the following morning uræmic coma was complete, and she died in the evening.

Autopsy, made twenty four hours after death. All the organs were normal except the kidneys, which presented the characteristic changes of acute parenchymatous nephritis. No evidences of old or recent tubercular changes were found.

Inoculation Experiments and Results.—Three bronchial glands which had been removed were crushed and diluted with distilled water. Two cubic centimetres of the solution were at once injected into the right pleural cavity of a healthy rabbit. After July 14th the rabbit showed signs of failing health, and on July 24th it was killed. The pleural cavities were normal. A cheesy bronchial gland, as large as a small cherry, filled the posterior mediastinum. An old tubercular infiltration, which seemed to antedate the enlarged gland, involved the apex of the right lung. A small circumscribed eruption of recent tubercles involved the upper portion of the left lung. The rest of both lungs was normal. In the liver a few small miliary tubercles were seen on the surface, while the spleen, stomach, and intestines were completely studded with miliary tubercles.

The apparently normal bronchial glands of this young woman, who had been in perfect health until a short time before death, and living under good hygienic surroundings, furnished a solution which, when injected into a healthy rabbit, produced general tuberculosis. At the autopsy this rabbit presented appearances similar to those which are found in rabbits inoculated with a pure culture of the tubercle bacilli, and in its turn furnished, on sterilized potatoes, an equally pure culture of the bacilli.

CASE VI.—G. W——, aged thirty-eight, who had been drinking heavily for three weeks, was found in an unconscious condition on the street, and taken to the alcoholic ward of Bellevue Hospital. He died in four hours.

Autopsy, made ten hours after death. No lesion was found in any of his organs, with the exception of the brain, which presented the characteristic appearance of the "wet brain;" and the pancreas, which was twice the normal size, and, under the microscope, showed extensive areas of hemorrhagic necrosis. There were no evidences of any tubercular processes in any part of the body. Six small bronchial glands were removed.

Inoculation Experiments and Results.—A healthy rabbit was inoculated with 1½ c.c. of the fluid obtained from the glands. At the end of six weeks the rabbit was

killed, and every organ was found in a perfectly healthy condition. The microscopic appearance of the pancreas resembled to some degree the appearance produced by tuberculosis, but a number of sections made from various portions of the organ showed that the necrotic-looking areas were composed of degenerated fibrin and blood-corpuscles, with some broken-down pancreatic tissue. No microscopical resemblance to tubercles was found. This case was presented before the New York Pathological Society.

CASE VII.—Frederick W——, aged thirty-five, of robust physique, who had been in the habit of going on periodical sprees for the past six years, was brought into Bellevue Hospital with the symptoms of acute alcoholism, and died twenty hours after admission.

Autopsy, ten hours after death. The kidneys presented the lesions of chronic interstitial nephritis; the left heart was hypertrophied; the pericardial sac contained eight ounces of clear serum, and the brain presented the ordinary appearance of the "wet brain" of alcoholism. The other organs were normal and no old or recent tubercular lesions were found. Six bronchial glands were removed, one of which was greatly enlarged.

Inoculation Experiments and Results.—A healthy rabbit was inoculated in the right pleural cavity with 3 c.c. of the fluid obtained from the glands, and was then turned loose in the yard. Eight weeks later the rabbit was killed, and the right lung showed the characteristic lesions of diffuse tubercular infiltration most marked in the lower lobe. The right lung was less extensively but similarly involved. In many places in both lungs the tubercular infiltrations had undergone cheesy changes. On the parietal pleura were seen a few typical tubercles. The other organs presented a normal appearance.

The lesions found in the inoculated rabbit were so characteristic of tuberculosis that a control inoculation seemed unnecessary, and it was not performed.

CASE VIII.—J. D——, aged sixty, was in perfect health until six days before his death, when he suddenly became unconscious, and presented the usual symptoms of cerebral apoplexy.

Autopsy, made twenty hours after death. All the organs were found normal, except the heart and brain. The heart showed slight atheroma of the aortic valves, with moderate dilatation of the left ventricle. The brain contained in its left hemispere a recent blood-clot, which involved the second and third frontal convolutions. No evidence of tuberculosis was found in any part of the body.

Inoculation Experiments and Results.—A healthy rabbit was inoculated in its peritoneal cavity with 4 c.c. of the fluid obtained from six bronchial glands. Six weeks afterward the rabbit died, and a localized chronic peritonitis was found, limited to the upper portion of the abdominal cavity. There were cheesy masses containing pus over the liver and stomach, which presented all the microscopical appearances of tubercular abscesses, but repeated examination of these masses failed to reveal the presence of any tubercle bacilli. The abdominal glands were enormously enlarged; with this exception, the rabbit presented a normal appearance. A second rabbit inoculated died at the end of six days from septic infection.

There is no evidence that the bronchial glands removed from this case contained tubercle bacilli; the animal inoculated evidently died of non-tubercular peritonitis.

CASE IX.—George E——, aged thirty-eight, stevedore, while engaged in unloading a vessel, was instantly killed by the falling of a beam.

Autopsy, made twenty hours after death. All the organs were found in a normal condition, with the exception of extensive adhesions over the upper lobe of the left lung. A careful examination failed to reveal any old or recent tubercular processes. Death was due to an extensive depressed fracture of the skull, beneath which was a large hæmatoma. There was also fracture of three of the ribs. Six normal-looking bronchial glands were removed.

Inoculation Experiments and Results.—A healthy rabbit was inoculated in the right pleural cavity with 5 c.c. of the fluid obtained from the glands. Eight weeks later the rabbit was killed, and with the exception of adhesions and pigment deposits (from the injected fluid) over the lower lobes of the right lung, all the organs were in a normal condition. In this case the large amount of fluid injected seemed to have excited an adhesive pleurisy. The fluid was absorbed, but the pigment derived from the bronchial glands, in this, as in many of the other cases, remained at the bottom of the pleural sac, or was distributed along the lymphatic vessels of the pleura in delicate black lines. The lungs presented no evidence of tuberculosis.

CASE X.—D. M——, aged sixty-six, who had suffered over a year with cardiac symptoms, died suddenly.

Autopsy, made eighteen hours after death. Extensive disease of the aortic and mitral valves was found, with dilatation and hypertrophy of the left ventricle. The liver and kidneys were small and cirrhotic. With the exception of intense congestion and œdema of the lower lobes, the lungs were perfectly normal. Six bronchial glands were removed, one of which was very large, pigmented and fibrinous looking.

Inoculation Experiments and Results.—Four cubic centimetres of the fluid obtained from the glands were injected into the right pleural cavity of a healthy rabbit. At the end of six weeks the rabbit, which had become very much emaciated, was killed. The left lung was normal, but the right was completely consolidated, and bound to the chest-wall. Single and collected nodules projected from the surface, and studded the pulmonary tissue. Three small cavities were noted at the base. A nodule as large as an olive, containing grumous material and creamy-looking pus, completely filled the right lobe of the liver. Two nodules, the size of millet seeds, were found in the right kidney. The mesenteric glands were enlarged and pigmented. A second rabbit was inoculated in the right pleural cavity with material obtained from the first, and died at the end of seven weeks, with the characteristic lesions of miliary tuberculosis.

CASE XI.—James D——, aged forty-six, of strong, vigorous physique, was admitted to the hospital with the symptoms of lobar pneumonia, and died on the fourth day of the disease.

Autopsy, made twelve hours after death. The kidneys showed the lesions of a moderate amount of interstitial nephritis. The liver was fatty and cirrhotic. The lower lobe of the right lung was in the third stage of pleuro-pneumonia. The other organs were normal, and no evidence of old or recent tubercular lesions could be found. Six bronchial glands were removed. One was enlarged, and contained a calcareous mass.

Inoculation Experiments and Results.—The glands were prepared in the usual way immediately after removal, and 4 c.c. of the fluid obtained were injected into the right pleural cavity of a healthy rabbit. Six weeks afterward the rabbit was killed, and with the exception of complete obliteration of the right pleural cavity by organized adhesions, and a collection of pigment in its lower portion, all the tissues were in a normal condition.

There is no evidence that in this case the bronchial glands contained tubercle bacilli, although one gland was very much enlarged, and contained a calcareous mass, showing that it must have been at some time the seat of cheesy metamorphosis. These glands were not placed in paraffine in the usual way, yet no septic infection of the rabbit followed the inoculation, and the large amount of fluid injected (5 c.c.) produced no other result than an acute adhesive pleurisy.

CASE XII.—Fanny W——, aged seventeen, when in excellent health, was attacked with acute pericarditis and died on the sixth day.

Autopsy, made fourteen hours after death. All the organs were perfectly normal, except the heart, which presented the usual characteristic lesions of acute serofibrinous pericarditis. A careful examination of the lungs and pericardium excluded the possibility of tubercular infection. Five normal-sized bronchial glands were removed.

Inoculation Experiments and Results.—Three cubic centimetres of the fluid obtained from the glands were injected into the right pleural cavity of a healthy rabbit. Ten weeks afterward the rabbit was killed. All the organs were found normal, except the liver, which contained the cicatrix of an old abscess, and a few nodules of cheesy degeneration. The right pleural cavity contained a small amount of clear serum. One of the larger nodules from the liver was inoculated into the right pleural cavity of a healthy guinea-pig. At the end of ten weeks the animal was killed, and its organs were found perfectly normal.

This case not only showed that no tubercle bacilli were demonstrated in the bronchial glands removed from the young woman, but that the pericarditis was non-tubercular.

CASE XIII.—Robert H——, aged twenty, was in perfect health until attacked with typhoid fever. In the third week of the disease he died.

Autopsy, made eighteen hours after death. Ulcers were found along the lower portion of the small, and the beginning of the large, intestines, but they did not have the characteristic appearance of typhoid ulcers. The spleen was enlarged and softened, and from its substance a pure culture of the typhoid bacillus was obtained in gelatine, proving definitely the character of the disease. The rest of the organs were normal, with the exception of a number of easily detached adhesions which bound the right lung to the chest-wall.

Six small bronchial glands were removed, also four inguinal glands.

Inoculation Experiments and Results.—Immediately after the removal the bronchial and inguinal glands were reduced to pulp in separate crucibles, and 4 c.c. of the fluid obtained from each were injected respectively into the right pleural cavities of two healthy rabbits. Six weeks later the rabbits were killed, and the organs in both were found normal. In this case the inguinal glands were removed, together with the bronchial, in the hope of ascertaining whether, if the latter should prove to be tubercular, the inguinal would be similarly infected. A second series of experiments are now being conducted, with the object of ascertaining whether in cases where the bronchial glands contain no tubercle bacilli they may be lodged in other glands of the body.

CASE XIV.—A. D——, aged thirty-four, farmer, was admitted to Bellevue Hospital June 22d, after an illness of sixteen days. The diagnosis of trichina poisoning was made. The patient died on the fourth day after admission.

Autopsy, made four hours after death. The tissues were found normal, with the exception of some of the voluntary muscles and the intestines. Microscopical examination of the muscles showed encysted trichinæ. No tubercular process was found on any part of the body.

Eight bronchial glands of normal appearance were removed.

Inoculation Experiments and Results.—The glands remained in paraffine for twenty-four hours, when a healthy rabbit was inoculated with 3 c.c. of the fluid obtained. Nine weeks later the rabbit was killed, and all its organs were found normal.

CASE XV.—F. F——, aged forty-five, was found dead by the police on the sidewalk of one of the down-town streets.

Autopsy, made fourteen hours after death. The kidneys were typical examples of the "small cirrhotic kidney." The left heart was hypertrophied and showed no valvular lesion. The lungs were normal, and no evidence of any old or recent tubercular process was found in the body. The brain was not examined.

Experimental Inoculation and Results.—The four bronchial glands removed were slightly enlarged and very much pigmented. Three cubic centimetres of the fluid obtained were injected into the right pleural cavity of a healthy rabbit. Eight weeks later the rabbit, which had become much emaciated, was killed. Free pigment was found in the left pleural cavity, and over the surface of the lungs. Both lungs were firmly bound to the chest-walls by old adhesions, and in places fresh hemorrhages had occurred. A nodule the size of a pea was imbedded in the lower lobe of the left lung; about this was an extensive area of consolidation. The remainder of the lungs and the other organs were normal, with the exception of the liver, which contained six nodules, varying in size from a pin-head to a small cherry, with also a number of collections having the appearance of grains of sand. Microscopical examination of one of the larger nodules failed to reveal any tubercle bacilli.

The five larger nodules were reduced to pulp, the fluid was diluted, and 3 c.c. were injected into the right pleural cavity of a healthy rabbit. At the end of seven weeks the rabbit was killed, and the right lung was found studded, especially in the lower lobe, with miliary tubercles. A number were also found in the liver and spleen, but none in the left lung.

The result of the inoculation of the second rabbit proved the impossibility of a positive diagnosis of the lesions in the first rabbit, by microscopical examination alone. The processes in this second rabbit were plainly tubercular, and the gland removed from the man proved to contain the tubercle bacilli.

CASE XVI.—Unknown man, aged about thirty-eight, was brought into Bellevue Hospital by ambulance. He died within eight hours and no history was obtainable.

Autopsy, twelve hours after death. The lungs were normal and no evidence of any tubercular process was found anywhere in the body. The man died from a rupture of an aneurism of the transverse portion of the arch of the aorta. Seven bronchial glands were removed, one of which was very much enlarged (two inches in diameter). One-third of this gland was preserved to examine microscopically for tubercle bacilli if the inoculation experiments should show that the rabbit died of tuberculosis.

Inoculation Experiments and Results.—Five cubic centimetres of the fluid obtained from the glands were inoculated in the usual way into a healthy rabbit. Three weeks after inoculation the rabbit had a litter of five healthy young. The rabbit was killed at the end of eight weeks and all the organs were found in a healthy condition.

CASE XVII.—Bridget N——, aged forty-eight, for a number of years a helper at the almshouse, while under the influence of liquor took by mistake an overdose of morphine and died within six hours.

Autopsy, twenty-four hours after death. All the organs presented by their gross appearance a normal condition, with the exception of an old patch of softening in the frontal lobe of the brain. Six bronchial glands were removed, one was enlarged and fibrinous looking, another contained a black, soft mass which looked like coagulated blood.

Inoculation Experiments and Results.—A healthy rabbit was inoculated with 3 c.c. of the fluid obtained from the glands. The rabbit was killed by an accident at the beginning of the fifth week of inoculation. An autopsy was at once made and, with the exception of localized adhesions over the right lung, all the organs were normal.

CASE XVIII.—Patrick M——, aged thirty-two, fell by accident from one of the wharves into the East River. He was rescued within a few minutes, but in spite of prompt treatment died at the end of two hours.

Autopsy, made ten hours after death at the request of the coroner. The man was of fine physique and in perfect health, all his organs being in normal condition.

The lungs presented the characteristic appearance of death by drowning.

Inoculation Experiments and Results.—Two and one-half cubic centimetres of fluid which was obtained from ten normal-looking bronchial glands removed from the case were injected into the right pleural cavity of a healthy rabbit. Seven weeks later the rabbit was killed and all the organs were found in a normal condition. There were no adhesions or pigment deposits to show where the needle was introduced.

CASE XIX.—Rosa S— —, aged forty, was found drowned at the foot of Morton Street. Nothing of her previous history is known.

Autopsy, made twenty four hours after body was found. The woman was robust looking and apparently had not been in the water many hours. All the organs were in a normal condition with the exception of the heart, which showed excessive left ventricle hypertrophy with no valvular lesion. Many of the arteries and especially the aorta were atheromatous. Five large gall-stones were found encysted in the gall-bladder. Ten bronchial glands were removed, one of which was very large and contained a cheesy mass the size of a cherry in its centre.

Inoculation Experiments and Results.—Three cubic centimetres of the fluid obtained from the glands, together with the cheesy centre of the enlarged gland, we reinjected into a healthy rabbit. Nine weeks later the rabbit was killed. It was found that the fluid had been injected by mistake into the upper portion of the peritoneal cavity behind the right lobe of the liver. At the point of inoculation there was no evidence of any inflammatory change beyond a small patch of prithysabitis. The lymphatics of the posterior abdominal wall were beautifully mapped out by the pigment derived from the glands. All the organs of the rabbit were in a perfectly healthy condition. This case shows two interesting points: First, that the enlarged cheesy gland contained no tubercle bacilli, for the whole mass was reduced to a fluid and injected; second, that the injection was perfectly harmless, producing no inflammation or adhesions.

CASE XX.—Michael F——, aged forty-five, died of lobar pneumonia, on the seventh day of the disease. Before his last illness he had always enjoyed the best of health.

Autopsy, twenty-eight hours after death. The lower lobes of both lungs were in the second stage of lobar pneumonia. Old adhesions bound the left lung in places to the chest-wall. With these exceptions all the organs were in a normal condition. Eight fibrinous looking, but only slightly enlarged, bronchial glands were removed.

Inoculation Experiments and Results.—Five cubic centimetres of the fluid obtained by preparing these glands in the usual way were inoculated into a healthy rabbit. Seven weeks afterward the rabbit was killed, and at the autopsy the following condition was found: The right lung was bound to the chest-wall throughout its whole extent. Four or five masses projected from the surface and extended into the substance of the lower lobe of the right lung. These nodules were surrounded by consolidated areas and had all the appearance of being tubercular. There was a mass the size of a large cherry behind the lungs which contained a whitish cheesy material. This I believe to have been an enlarged tubercular bronchial gland, although stained cover-glass preparations of the cheesy material failed to reveal any tubercle bacilli. The left lung was normal, as were also the abdominal organs.

A rabbit which had been inoculated from the first rabbit died by an accident before any conclusion could be reached, so we have no positive way to prove that the lesions of the first rabbit were tubercular. From a careful examination of a number of sections I feel almost certain that the changes found were those of a localized tuberculosis, but I have not included this case with those which had tubercle bacilli in their bronchial glands.

CASE XXI.—S. C——'s child, aged two and a half years, was always perfectly well to within ten days of its death. The diagnosis of general capillary bronchitis was made, but the question of tuberculosis being raised an autopsy was requested.

Autopsy, made twelve hours after death. All the organs were found in a normal condition, with the exception of the lungs, which showed the lesions of catarrhal pneumonia secondary to a general bronchitis. No tuberculosis was found. Seven normal-looking bronchial glands were removed and kept for six hours wrapped in a cloth soaked in a solution of carbolic acid.

Inoculation Experiments and Results.—Three cubic centimetres of the fluid obtained from the glands were injected in the usual way into a healthy rabbit. Eight weeks later the rabbit was killed and all its organs were found in a normal condition. There was localized adhesion of the lung at the point where the needle pierced the chest cavity.

CASE XXII.—Mary M——, aged seventy two, died of senility, at the Workhouse hospital. She was well nourished and had been confined to her bed only one week.

Autopsy, made twenty-four hours after death. About a pint of clear serum was found in the right pleural cavity. The lungs were normal, with the exception of œdema and congestion of the lower lobes. The liver and kidneys both presented the lesions of an old interstitial change (cirrhotic). Five enlarged bronchial glands were removed.

Inoculation Experiments and Results.—Three cubic centimetres of the fluid obtained from the glands were injected into the right pleural cavity of a rabbit. The rabbit, which had remained perfectly well, was killed at the end of eight weeks. The thoracic organs were normal. The abdominal cavity contained a small amount of clear serum. Throughout the liver were a number of very small whitish gray points, having very much the appearance of miliary tubercles. However, a microscopical examination of these masses showed that they were not tubercles, but small capillary infarctions (mechanical).

The enlarged glands removed from this case contained no tubercle bacilli, although the gross appearance of the lesions found in the rabbit's liver was very similar to that of tuberculosis. The microscopical examination, however, showed these not to be tubercular.

CASE XXIII.—Anna H——, aged twenty-two, was admitted to Bellevue Hospital suffering from cardiac disease. Her friends said she had been perfectly well to within two weeks of her admission, when she was obliged to take to her bed on account of shortness of breath and severe pain and palpitation over the heart. Cardiac asystolium was pronounced, and it was impossible to accurately diagnose the loud blowing murmurs heard over the præcordial region. She died at the end of ten days.

Autopsy, twenty-four hours after death. There was extensive ulceration and reversion of the aortic valve, with fibrinous deposits on the free surfaces. The lesion was apparently an acute ulcerative process engrafted on an old lesion of the aortic valve. All the rest of the organs were normal, with the exception of the lower lobes of the lungs, which showed the lesions of hypostatic congestion.

Inoculation Experiments and Results.—Eight bronchial glands of normal size and free from pigment were prepared in the usual way and 5 c.c. of the fluid were injected into a healthy rabbit. The rabbit died on the fortieth day after inoculation. At the autopsy it was found that the fluid had been introduced into the upper portion of the peritoneal cavity. An adhesive peritonitis had been set up, and a large abscess formed to the right and behind the liver filled with grumous pus. The thoracic organs were normal, although the abscess had not the appearance of a tubercular abscess. Still, to settle the question, a second rabbit was inoculated with some of its contents. All the organs of this rabbit, which was killed at the end of six weeks, were found normal. The bronchial glands removed from this case contained no tubercle bacilli, and the peritonitis and abscess found in the

inoculated rabbit were not tubercular, as was proven by the control experiment.

CASE XXIV.—Patrick B——, aged thirty-eight, had complained of heart trouble for a long period, but was able to be about and attend to his business to within eight days of his death. During the last week the symptoms of acute endocarditis developed, accompanied by high fever and a rapid pulse.

Autopsy, twenty hours after death. All the flaps of the aortic valve presented the lesions of an acute exudative process engrafted on a chronic lesion. In the lower lobe of the right lung, close to its root, was found a small circumscribed abscess, the result of an infarction, with this exception the lungs were perfectly normal. There were no evidences of any tubercular changes. Two large infarctions were found in the spleen, together with a few small ones in the kidneys. All the bronchial glands were very much enlarged and softened. The case was one of acute ulcerative endocarditis. Micrococci were found in stained sections cut from the aortic valve.

Inoculation Experiments and Results.—Fourteen bronchial glands were removed and 3 c.c. of the fluid obtained from them were injected into a healthy rabbit. After seven weeks the rabbit was killed. The lymphatics of the right pleural cavity were beautifully mapped out by the injected gland pigment. With the exception of localized adhesions at the point where the needle had pierced the chest cavity the lungs were perfectly normal. A few small nodules the size of a pin's head were found in the liver, but a microscopical examination showed them to be not tubercles but emboli in the vessels. This case showed by the inoculation experiments that the bronchial glands were free from tubercle bacilli, and also that the enlarged bronchial gland close to the embolic abscess in the lungs contained no septic micro-organisms, or not enough to cause the rabbit's death from septicæmia.

CASE XXV.—Michael M——, aged thirty-two, while in perfect health, fell from a third story window upon the pavement below and died immediately from fracture of the skull.

Autopsy, made twenty-eight hours after death. All the organs were found in a normal condition. Five bronchial glands were removed, one of which was about twice the normal size.

Inoculation Experiments and Results.—Five cubic centimetres of the fluid obtained from the glands were injected into the right pleural cavity of a healthy rabbit. Eight weeks afterward the rabbit, which had become emaciated, was killed. A large, completely encysted abscess was found filling the right pleural cavity, producing collapse of the lung. The cavity of the abscess contained a thick, grumous, whitish-gray pus, and had somewhat the appearance of a tubercular abscess. The left lung was normal, as also were the rest of the organs, with the exception of two or three suspicious little nodules in the liver. One of these, together with some of the fluid from the abscess was injected into the right pleural cavity of a second rabbit. This rabbit was killed at the end of two months, and all its organs were found in a perfectly normal condition. The pleural cavity showed no evidence of the injection.

The result of the inoculation of the second rabbit proved conclusively that the nodules and abscess found in the first rabbit were not tubercular, and also that even the enlarged bronchial gland removed from the man was free of tubercle bacilli.

CASE XXVI.—G. W——, aged thirty-five, went to bed in one of the uptown hotels in apparently perfect health. He blew out the gas and was found dead in the morning.

Autopsy, made thirty-two hours after death. Body well nourished, blood fluid, œdema and congestion of the lungs. There was thickening, but no adhesions, of pleura over right apex; with this exception the lungs were normal, as were all the rest of the organs.

Six bronchial glands were removed, all of them being very much enlarged, and one measured 4 inches in length and 1½ inch in diameter, and contained a cheesy, calcareous, tubercular looking mass.

Inoculation Experiments and Results.—Four cubic centimetres of the fluid obtained from the glands, including the cheesy mass found in the large gland, were injected into the right pleural cavity of a large healthy rabbit. Seven weeks later the rabbit was killed. It was well nourished and apparently healthy. Organized adhesions were found obliterating the right pleural cavity; the lung was collapsed. The appearance was as of an old pleurisy with absorption of the fluid. The lung was normal, as were the rest of the organs. No evidence of tuberculosis was found anywhere.

In this case all the bronchial glands were greatly enlarged, and one had the appearance of being tubercular. Still, the inoculation experiment proved it not to be so. This case shows how one might be led into error by relying upon gross appearance alone.

CASE XXVII.—Female, aged fifty, was found in the street in a stupid condition, due, as supposed, to the effects of liquor. She was brought to the hospital by ambulance where she died at the end of twelve hours, without regaining consciousness.

Autopsy, thirty-six hours after death. In the brain were found two small clots; one involving the anterior and under portion of the occipital lobe on the right side, the other the island of Reil and the overlapping parietal lobe. All the cerebral arteries were atheromatous. The left ventricle was markedly dilated; there were no valvular lesions. Kidneys cirrhotic; liver slightly "fatty." There were a few old adhesions over both lungs, but no old or recent tubercular changes were found in their substance. Ten bronchial glands were removed, about normal in size and very much pigmented. Two of the glands were about three times the normal size and fibrinous looking.

Inoculation Experiments and Results.—The glands were prepared in the usual way. Two cubic centimetres of the fluid were injected into a healthy rabbit. Seven weeks after inoculation the rabbit was killed. The right pleural cavity presented a normal appearance, except where the needle was introduced. There was connective tissue increase, and on the costal pleura were ten or fifteen tubercles the size of a pin's head. In the right lung a number of tubercular nodules, varying in size from a pin's head to a pea, were found; one of these nodules was quite large and contained a cheesy centre. In the left lung only a single small tubercular mass was found. A few tubercles were found in the substance and on the inferior surface of the left lobe of the liver. The rest of the organs were normal.

This patient was stricken down in the street with an apoplectic stroke, and was, as far as could be learned from her friends, in good health at the time of her death. The lesions found in the rabbit inoculated with the bronchial glands were so characteristic and so evidently started at the point of injection that an inoculation of a second rabbit was not deemed necessary.

CASE XXVIII.—George M——, aged thirty-five, was admitted to Bellevue Hospital May 2d. He had been sick, as he expressed it, "off and on" for nearly a year. For the past month he had been confined to the house and unable to work. There were well-marked symptoms of cardiac disease and an excessive enlargement of the liver and spleen. Two weeks after admission the patient died, becoming intensely jaundiced toward the last.

Autopsy, made twelve hours after death. The lungs were perfectly normal, with the exception of some old adhesions over the right side, especially at the apex, and an encysted fibrinous looking nodule the size of an olive at the left apex. The heart showed the lesions of an acute endocarditis engrafted on a chronic lesion. The liver weighed eleven and one half pounds and was amyloid, as was also the spleen. No tubercular lesions were found anywhere in the body, with the exception of the

nodule at the apex, which presented the appearance of a healed phthisis. Ten bronchial glands of normal size, and with the exception of two, of normal appearance, were removed. On opening these two glands, small cheesy masses were seen scattered throughout the gland; by squeezing the gland they protruded, as "little white worms." Eight of the enlarged mesentric glands were also removed.

Inoculation Experiments and Results.—Four cubic centimetres of the fluid obtained from the bronchial glands were injected in the usual manner into a healthy rabbit, and another rabbit was also inoculated with equal amount of fluid obtained from the mesenteric glands. Six weeks later the first rabbit was killed and all the organs were found to be healthy. A small mass was found attached to the ribs at the point of puncture. There were no adhesions and an examination showed it to be composed entirely of new connective tissue.

The rabbit inoculated from the mesenteric glands was also killed, and all its organs were found in a normal condition.

A microscopical examination of the nodule found in the lungs showed the ordinary appearances of a tubercular process which had been recovered from by new connective tissue formation. The experiments proved, first, that if the bronchial glands had ever contained tubercle bacilli, they were free from them at the time of death, and that the white cheesy masses found in two or three of the glands were non-tubercular in character, second, that the mesenteric glands contained no tubercle bacilli.

Case XXIX.—Henry F——, aged forty-eight, died after a prolonged sickness of advanced cardiac and Bright's disease.

Autopsy, made twenty hours after death. There was cardiac hypertrophy and dilatation with extensive lesions of the mitral valves. The lungs were normal, with the exception of an infarction, the size of a small apple, in the lower right lobe, which had gone to the formation of an abscess. The liver and kidneys were cirrhotic; all the tubercular glands were very much enlarged, soft, and extensively pigmented.

Inoculation Experiments and Results.—Three cubic centimetres of the black fluid obtained from ten of the glands were injected into a healthy rabbit. At the end of six weeks the rabbit was killed. A circumscribed, dense, pigmented mass was found on the surface and extending for a slight distance into the substance of the lower lobe of the right lung. There were no adhesions, but most of the lymphatics of the pleura on the right side were filled with pigment.

The mass in the lungs was due to the needle piercing the lung substance and setting up an inflammation which ended in the formation of new connective tissue. All the organs were normal and no evidence of tuberculosis was found.

I think the excessive enlargement of the bronchial glands in this case was due to the absorption from the encysted abscess cavity. They certainly contained no tubercle bacilli, nor did the rabbit show any of the lesions of septic infection from the glands.

Case XXX.—Nora S——, aged seventy, who had been a helper in the wards of Bellevue Hospital for over a year, suddenly became unconscious and died from what was supposed to be apoplexy.

Autopsy, made fourteen hours after death. The cause of death was found to be due to a hemorrhage into an old degenerated area in the corpus striatum. There was also excessive cardiac dilatation. The lungs were perfectly normal, with the exception of excessive pigmentation. Eight bronchial glands were removed, one of which was very large and fibrinous looking; all were dense and pigmented.

Inoculation Experiments and Results.—Two cubic centimetres of the fluid obtained in the usual way from the glands were injected into a full-grown, healthy guinea-pig. One week after inoculation the animal began to lose flesh and appetite, and failed steadily in health for two months after inoculation, at which time it was killed.

The animal was very much emaciated. On opening the chest both lungs were found studded with tubercles, and tubercles the size of a pin's head were seen all over the costal and diaphragmatic pleura and both surfaces of the pericardium. The liver and spleen were completely destroyed by cheesy, tubercular masses.

This is one of the most interesting cases collected. The woman was under observation for a long time and always seemed to be perfectly well, although somewhat enfeebled by her age. She spent her time in a ward where there were many phthisical cases. She died suddenly. Her lungs were normal, being even entirely free from adhesions. One bronchial gland was very much enlarged, and was the seat of a chronic inflammation. This gland unquestionably, and possibly also some of the normal sized ones removed, contained tubercle bacilli, as the animal inoculated died of well-marked general tuberculosis.

General Review of Cases.—The period of experimentation extended over eighteen months. During this time the substance from the bronchial glands removed from forty-eight persons was injected into healthy rabbits, which were kept under the best hygienic conditions. The majority of these forty-eight persons died suddenly, and none of them after a prolonged illness. A careful examination of all the organs in such persons failed to reveal any old or recent tubercular process. Eighteen of the forty-eight experimental inoculations were failures, for the rabbits died before any tubercular infection, if present, could have shown itself, consequently these have not been included in the thirty from which my conclusions are drawn. The bronchial glands removed from eight of the thirty cases contained tubercle bacilli, as demonstrated by the development of tuberculosis in rabbits inoculated with the substance of the bronchial glands. In five of these eight cases death occurred suddenly from accident, while they were in apparent health, and none of the thirty, with two exceptions, were sick more than ten days. Three of the twenty-one negative cases caused lesions in the inoculated rabbits, which resembled so closely tubercular nodules that the inoculation of a second rabbit was necessary to determine their non-tubercular character. The results of the inoculation of the gland substance in Case II. illustrates in a striking manner the possible presence of tubercle bacilli in the bronchial glands in persons of strong and vigorous physique, and in the fullest physical activities of adult life. Cases I. and V. furnished, in the fluid obtained from their bronchial glands, enough tubercle bacilli to set up in the rabbits inoculated a military tuberculosis, from which pure cultures of the tubercle bacilli were made on sterilized potatoes.

Cases VII. and X. both produced in the rabbits inoculated a profuse pulmonary tuberculosis.

While the gland substance in Case XV. contained tubercle bacilli, the lesions found in the first rabbit could only be rendered positive by the inoculation of a second rabbit. In almost all the cases inoculated the pigment contained in the glands was seen in the rabbits at the point of injection, and it spread out along the lymphatic channels, which were beautifully mapped out by it.

There is one point we must not lose sight of in the analysis of these cases: they were principally taken from the lower walks of life, most of them hospital cases. Such persons must necessarily be surrounded by impure air, and are more exposed to the possible inhalation of tubercular bacilli in large numbers than are those who, in large and well-ventilated apartments, live under better hygienic surroundings.

Case XXVII. furnished bronchial glands from a person suddenly stricken with apoplexy in apparently perfect health. These glands contained tubercle bacilli, which would have caused the death of the inoculated animal from tuberculosis if it had been permitted to live long enough.

Case XXX. is exceedingly interesting from two facts: First, the patient had spent the last year of her life in apparently good health in a hospital ward, surrounded by phthisical patients. She died suddenly. Second, her bronchial glands furnished such an intense tubercular virus as quickly to overpower the inoculated animal by a general tuberculosis.

A CONTRIBUTION TO THE STUDY OF NIGRITIES.

By J. A. HOFHEIMER, M.D.,

PHYSICIAN TO HARLEM HOSPITAL DISPENSARY, NEW YORK.

THIS disease, variously known as nigrities, glossophytia, black tongue, or glossitis parasitica, is one which is not commonly met with. The writer having recently had the opportunity of treating a case, herewith presents a report of it.

Mrs. X——, aged thirty-one, had been under treatment for sciatica, and claims to have only been relieved by the use of opiates, which she took in the form of suppositories. She had consulted the writer in regard to a disordered stomach, and complained of a bad taste in the mouth accompanied by foul breath. The gastric distress disappeared under treatment, but patient's tongue was still furred and breath foul. Shortly afterward, about the early part of April, 1890, the lady complained of a sour taste, and a "thick feeling in her mouth," also calling my attention to her tongue. Examination revealed the tongue to be of a deep black color on the dorsal surface, and coated with a slimy mass; on scraping some of this off it was found to have a very fetid odor, and the papillæ of the tongue were so elongated that they waved to and fro like grass in a wind storm. The papillæ were almost jet black at the top, shading into a brown farther down, and grayish at the base. The tongue was slightly swollen, but not tender. The entire dorsum was involved. A wash composed of soda biborate and glycerine was first used, with little or no effect. A strong solution (almost to saturation) of salicylic acid was then given as a wash; this had the effect of causing a desquamation of about two-thirds of the discolored epithelium, which came away like a piece of diphtheritic membrane. The surface denuded was raw and irritated in appearance. About a month later the trouble again recurred; but this time the wash which formerly did so much good had no effect. A lotion of soda salicylate and mercuric bichloride with glycerine used freely, succeeded in entirely removing the trouble; and in over four months no recurrence has been noticed.

In looking up the literature of this disease I find that it was first described by Salter in 1850, and though several excellent observers have recorded cases, it is a disease but seldom seen, yet one which will prove very troublesome to both patient and physician.

The true cause of the disorder is as yet undetermined. J. Solis-Cohen thinks it a default of nutrition; W. H. Thomson mentions a case in a physician who, after many years of coated tongue from dyspepsia, developed this disease. It lasted over a month and resisted treatment, but vanished soon after the patient left off eating strong English cheese for lunch. Buhn regards black tongue as of a parasitic nature, and probably dependent upon alterations of the normal micrococci present in the mouth forming a major part of the coating. He further states that the "amount of the micrococci is in inverse proportion to the food and epithelium present." Roth reports two cases in apparently healthy men. Scheet, however, denies the presence of a fungus, but maintains that it is a pigmented hypertrophy of the papillæ, which he finds are avoided by the ordinary micrococci of the mouth. He is not upheld in his opinion by the majority of writers on this subject, as the association of this disease with microorganisms has been almost constant. Two notable exceptions are found recorded—one a case of S. Solis-Cohen, in a negro child the subject of congenital syphilis; and Professor Bernhardt reports a case in which these patches had existed for thirteen years in a patient who had syphilis followed by locomotor ataxia.

The disease is characterized by a grayish or brown-black discoloration of the papillæ on the dorsum of the tongue; it is most marked at the apex of the papillæ and lighter toward the surface of the organ. The filiform papillæ are enormously enlarged and closely resemble hair. The individual papilla are surrounded by a parasitic vegetable growth; the irritation produced by this parasite causing longitudinal hypertrophy. Desois made culture-efforts to reproduce the disease upon his own tongue, but failed.

Cohen and Allen state there are no special subjective symptoms. But the former mentions that his patient complained of a sensation as if his mouth was full of hairs. Roth's two cases—one had breath of an acid odor and his tongue gave an acid reaction; the other had fetid breath for ten years. "There was no evidence of nasal or pharyngeal disease or carious teeth; but on scraping the tongue the odor was found to come from the coating." As one writer states, "this may prove another factor in the causation of foul breath" The objective symptoms are the general characteristics of the peculiar elongation and discoloration of the papillæ. Care should, however, be taken to exclude any discoloration from drugs or food.

As a rule the prognosis is favorable; but the disease is liable to recur, as in the writer's case, and in some cases has a tendency to chronicity. The affection lasts from a week to several months.

Notwithstanding that some writers on this subject have denied the presence of a parasite, and even Cohen, in his excellent article in Pepper's "System," from which I have largely quoted, states the possibility of there being two forms, one parasitic and the other non-parasitic, the fact remains patent that this disease has yielded to none other than parasiticides and antiseptics. Brosin, who argues that it is non-parasitic, finds the most efficacious treatment to be friction with Hebra's spiritus saponis, followed by the use of salicylic ointment, or a solution of salicylic acid in ether and collodion. Among the remedies used those which have found the greatest favor are salicylic acid or salicylate of soda used topically, either alone or in combination with mercuric bichloride 1 to 500. In Roth's case he used a ten per cent. solution of mercuric bichloride, and states that five applications apparently cured his patient. Washing the tongue with peroxide of hydrogen on absorbent cotton is also recommended. The treatment that will prove most effective is apparently the one which will quickly neutralize any acidity in the oral secretions, combined with some powerful antiseptic.

The writer has seen in private and dispensary practice a condition approaching nigrities, especially in cases with gastro-hepatic irritation, and which on using an antiseptic in addition to the usual remedies has disappeared. In these cases the preference has been for the internal administration of salol.

The case of the negro child with syphilis was controlled by potassic iodide without topical treatment, though it recurred at varying intervals.

New York, December 20, 1890.

THE STUDY OF THE KOCH METHOD.

IN the various hospitals here and elsewhere the theory of Koch is being subjected to the test of clinical study. Certain facts are being accumulated which have a tendency toward corroborating the observations of workers abroad. So far there appears to be a strange relation of cause and effect between the injection of lymph in tuberculous patients and a reactionary temperature proportionate to the amount of tuberculous deposit in the affected individual. Quite naturally this condition of things is made available for diagnostic purposes. How far the conclusions in regard to the latter property are sound remains yet to be proven by more extended experience. The same may be said concerning other phenomena noted in the different varieties of tubercular cases which have been subjected to treatment. Aside from mere assertion, and apart from theoretical inference, we have, from a purely practical stand-point, a great deal yet to learn. It becomes us, therefore, to be more than diligent in the collection of the data which shall enable us in due time to form strictly logical conclusions. Hence we are attentively observant and reasonably noncommittal. As we are driven before the gale of popular enthusiasm we must pause occasionally to take a reckoning and make soundings. Already we have touched shallow bottom in several places and must steer and trim accordingly. In the present stage of our study we have a reasonable idea of our actual position in not expecting too much. In fact we were told not to do so at the start. Koch himself, with becoming modesty, claims very little as yet. His theory, plausible as it may appear, is still to be demonstrated to the satisfaction of the working clinician. In the meanwhile abundance of time must be allowed for the accumulation of the necessary experience upon which to found our ultimate conclusions. The reported cures of incipient phthisis are not yet conclusive, as sufficient time has not elapsed to prove them permanent. Enough has been said and done, however, to encourage us in our work of inquiry. When we learn that in such cases, after repeated inoculations with the lymph, physical signs disappear, general phthisical symptoms cease, and the tubercle bacilli are no longer found in the sputa, we become more than hopeful for the verification of such novel and startling facts. The reported action of the inoculated lymph upon lupus and tubercular glands is certainly very strange, and whether we accept the theory of its action or not, the facts noted are of great clinical importance.

The supposed elective affinity of the lymph for bacillary deposits is not, analogically speaking, impossible, and adds enough of novelty to our present reasoning to give increased zest to our clinical studies.

While we hope for the best in obtaining tangible results, it is to be deplored that we are still in the dark as to the actual composition of the fluid for which such wonderful properties are claimed. We are thus debarred the use of an important factor in our estimation of results, and denied the opportunity of studying the *rationale* of a scientific problem in all its proper and varied bearings. In the interest of the freest possible spirit of inquiry, which is alike the necessity and pride of true science, we trust that the jealously guarded secret will soon be disclosed. In the meantime we must, under the circumstances, be contented simply to collect isolated facts and interpret them as best we can. This much certainly will be done, in view of the incentives for renewed study which are now offered, and in the end much good may be accomplished, even though the Koch method may prove a failure. The harvest is plenty, and the laborers are not few.

THE RELIEF OF PRURITUS.

ITCHING is of various kinds, and depends upon a great variety of cutaneous lesions. In some instances there are no eruptive features connected with sensation, and we have an independent disease without eruption, excepting such as continual scratching will produce. In the RECORD of October 18th, we published a scientific study of "The Sensation of Itching" from the pen of Dr. Bronson, which points out the reasons why people itch. What will stop the itching is a question which is of equal interest both to the sufferer from pruritus and the physician called upon to relieve it.

Dr. Bronson tells us, among other things, "that scratching relieves itching by directing the excitation into freer channels of sensation sometimes, especially when severe, substituting for the pruritus either painful or voluptuous sensations." It is scarcely ever necessary for the physician to prescribe this means of relief. It has been a household remedy for ages, and the infant has mastered its application before it graduates from the cradle. More frequently we have to order our patients not to scratch, because the relief attending the act is evanescent, and the damage done to the skin in a moment may take weeks or months to repair.

It is needless to say that this injunction can frequently not be enforced by any means short of the straight jacket.

Fortunately there are a few, out of the many recommended, drugs for the relief of pruritus, which have a more or less pronounced and lasting effect.

Menthol is not a new remedy in this sense, but it has of late received considerable attention. Dubreuil and Archambault have studied its effects in a variety of pruriginous affections, and find that with it they can succeed in calming itching of whatever nature it may be, but that it has its greatest effect in those cases where scratching provokes or keeps up the lesion of the skin and the pruritus. This

is particularly true of urticaria, certain eczemas, and the pruritus following scabies after the itch mites have been destroyed.

In urticaria a ten per cent. solution in alcohol or almond-oil can be employed, and in the acute and subacute forms is said to be capable of bringing about a speedy cure. For itching eczemas a five to ten per cent. solution in oil may be used, or from two to five per cent. of menthol may be added to oxide of zinc ointment. Upon excoriated surfaces and mucous membranes, care must be exercised not to use too strong applications, as a disagreeable sensation of burning may be determined, and for such parts an oily rather than an alcoholic solution should be chosen. Again, applications should not be made to the whole surface at once, since the sensation of cold which accompanies the anæsthetic action is in some cases extremely disagreeable.

In pruritus ani, perineal and genito-crural eczema, the results of treatment by menthol are said to be very favorable. We must not confound pruritus, as a symptom of numerous cutaneous diseases, with pruritus, an independent disease of nervous origin. In the former the underlying skin affection must be treated in an appropriate way, while anti-pruritics are relied upon to secure as much relief as possible. And all relief given from the itching is so much gained toward permanent cure. The consolation of the text "Blessed are they who itch, for they may scratch," may have sufficed for olden times, but the scientific spirit of to-day requires of us better things.

THE PATHOLOGY OF THE BLOOD.

The recent discoveries of Koch, by which it would appear that immunity against certain infections can be obtained by injections of the blood of animals already protected, are likely to give renewed interest to the extraordinary properties of this fluid. Never so much as now does the blood seem to be "a most peculiar juice."

In the last few years the additions to our knowledge of the pathology and physiology of the blood have been especially rich. The fact of the existence of a third corpuscle or blood-plaque has been quite absolutely established. Some new facts showing the natural history of the red corpuscle and its development out of the white, have been contributed by Ranfer and others. Many important studies have been made upon the chemistry of the blood, and upon the alleged germicidal properties of the serum.

Loeffler has shown it to be probable that a lessened alkalinity of blood is a factor in the susceptibility to infection, and explains in this way the greater liability of children to infective fevers.

The existence of the plasmodium malariæ in the red blood-cells has become a recognized and important clinical and diagnostic phenomenon.

At the third Italian Medical Congress, held October 20th in Rome, a large part of the time was taken up in discussing the various problems of blood pathology, and the question was raised whether this fluid might not have primary and "essential" diseases, like other tissues of the body. It was suggested that malaria might be a disease of this kind. The microbicide action of blood was also discussed. It was agreed that blood does have an action in this direction.

Catello said that he had found that in acute pneumonia the microbicide action of blood-serum is very pronounced, while it is considerably diminished in diabetes.

Rovighi had found that the microbicide action of human blood varied according to the microbes. It was, for instance, considerable with respect to the bacilli of typhoid fever, and less in respect to the staphylococcus aureus. It diminished in dyscrasic states with destruction of the red corpuscles, and varied according to temperature, being destroyed by very high or very low temperature.

We should not fail to mention in this connection the advances in the technique of blood examinations. It is now not at all difficult for the general practitioner to estimate the number of corpuscles and the percentage of the hæmoglobin. A study of these two factors has led certain writers to make a very definite classification of what may be called the anæmias.

Thus in simple anæmia there is a diminution in red blood-cells, and also in hæmoglobin. In pernicious anæmia the number of corpuscles is lessened, while the hæmoglobin is relatively increased; and in chlorosis the number of red cells is normal, but the hæmoglobin is decreased in amount.

We have put together the foregoing facts somewhat disconnectedly, but they will, we believe, impress our readers with the interest which the pathology of the blood is now exciting, and the great practical importance attached thereto.

THE LOST THREE MILLIONS.

All the world has been discussing the decline in birth-rate and forthcoming depopulation of France. The phenomenon has been regarded as both unfortunate and peculiar. But if our last census is correct, a somewhat similar process is beginning with us.

Here are the facts as given:

Between 1870 and 1880, with an immigration of 2,707,000 only, the increase of population is 11,598,000; so that, deducting the immigration, the increase which is due to the excess of births over deaths appears to be 8,891,000. Between 1880 and 1890, with an immigration of 5,275,000, the total increase of population is 12,225,000; and if we deduct the immigration, the increase which is due to the excess of births over deaths appears to be 6,950,000 only! The excess of births over deaths, which was nearly 9,000,000 between 1870 and 1880, falls to less than 7,000,000 in the following decade, although the population at starting was twenty-five per cent. greater in the later than in the earlier decade.

This can be best shown in a table, as follows:

	Increase of population.	Increase from births.
1870–80	11,598,000	8,891,000
1880–90	12,225,000	6,950,000

Thus the birth-rate has fallen off both absolutely and relatively. Assuming that this country had a birth-rate of 350 per 1,000 yearly, which is about the average of European countries, there would have been 20,000,000 births, and with a death-rate of 18 per 1,000, a little over

ten million deaths. We should expect that the increase of population through the birth-rate would have been nearly ten millions instead of nearly seven.

There are apparently three million babies wanting, either not born or not counted. The birth-rate of the past decade, according to the last census, is about the same as that of France, Ireland, and Greece.

It is not an impossible rate, but it is a pathological one. If it is correct, we are in the same condition essentially as France, viz., that of a sterile race, whose increase must depend mainly on the immigration. It will not do, however, to say flatly that the census is wrong, for there are many peculiar things about our population which make its growth a somewhat peculiar problem. Nearly half the adult population, for example, is now foreign-born, the proportion of women to men is unusually low, while the number of persons between the ages of thirty and fifty is much below the average, 221 per 1,000 as against 246. The question is one that ought to be studied dispassionately, but it has unfortunately got into politics, and a great many absurd statements are being made in consequence.

News of the Week.

Pasteur to Koch.—The following letter of congratulation, as generous and significant as it is brief, was addressed by M. Pasteur to DR. KOCH:

"Au DR. R. KOCH, à Berlin.

"M. Pasteur et les chefs de service de l'Institut Pasteur adressent à Rob. Koch toutes leurs félicitations pour sa grande découverte. PASTEUR."

[Translation.]

"To DR. R. KOCH, Berlin.

"M. Pasteur and the officers of the Pasteur Institute address their warmest congratulations to Rob. Koch on his great discovery. PASTEUR."

The New York Hospital Association Wins.—An action was commenced by the New York Hospital Association, some time ago, to have its farm of about three hundred acres in White Plains stricken off the assessment roll, on the ground that a special statute exempted from taxation all the property of the New York Hospital from which no income was derived. The case was tried before Justice Bartlett, and he decided against the hospital. An appeal was taken to the General Term of the Supreme Court, which has just handed down its decision in favor of the hospital. The Hospital Association will now go ahead and build its extensive buildings on the farm at White Plains.

Gold Hypodermic Injections in Phthisis.—Dr. J. Blake White read a paper before the Southwestern Medical and Surgical Society Wednesday evening, in which he described some remarkable effects from the use of the gold preparations administered hypodermically in tubercular affections, particularly external manifestations, and in persistent eruptions, especially of a leprous character. A committee was appointed, consisting of Doctors J. Lewis Smith, Simon Baruch, and Frank Grauer, to look further into the subject with Dr. Blake White. The paper will appear in a future issue.

An Analysis of Koch's Lymph by Professor Schnitzler, of Vienna, gives the following results (*Lancet*): It is a syrupy, slightly foaming liquid of brown color, its aqueous solutions showing a greenish fluorescence. In odor it resembles elder yeast or leaven combined with a sweet aromatic admixture such as honey. If slowly heated the smell of yeast gives way to an agreeable odor resembling fruits; on further heating the smell becomes like that of fresh bread crust, but without the acid character of fruit. If the heating of the substance is continued the smell assumes the empyreumatic character of that exhibited by burning albuminous matter and carbonizing horny substances. Only an extremely small quantity of ash (under one per cent.) was obtained. The liquid shows a neutral reaction. Some of the liquid was diluted with water and subjected to various tests. By adding diluted acetic acid it becomes slightly opaque, by which the presence of a small quantity of mucin is indicated; by further adding potassium ferrocyanide the opacity of the liquid is increased, showing the presence of albumin; but this reaction is too feeble to indicate the amount of the active principles in the lymph. On the other hand, the biuret reaction characteristic of peptones is very strongly marked. The tests for cyanogen compounds gave perfectly negative results, and the assumption that Koch has been using cyanides of gold or prussic acid seems therefore completely erroneous, as no metals could be detected in the liquid. Traces of reduction were observed after treating the liquid with Fehling's solution, but the presence of sugar among the reducing substances could not be confirmed. Sulphur and phosphorus in an organic form proved to be absent. As only a small quantity of the lymph could be used for chemical examination, it was impossible to shake the liquid with ether and alcohol for the purpose of separating the alkaloids, if present, from the albuminoids, but the reagents which reveal the presence of alkaloids and ptomaïnes even when mixed with albuminoids—*e.g.*, acid bichromate of potassium—failed to give a reaction, so that the absence of alkaloids and ptomaïnes may be taken for granted. It seems, therefore, that, besides the peptones, the principal active substances contained in Koch's lymph belong to that not yet chemically defined class of the protein bodies called toxalbumins, globulins, or enzymes, which play such an important *rôle* in all fermentative processes, from the chemical changes produced by common yeast in the products of the vegetable kingdom up to the coagulation of the blood in animals.

It is Stated that a meeting of the Board of Trustees of the *Journal of the American Medical Association* will soon be held, in order to take action upon the question of removing the *Journal* to Washington.

Large Superficial Veins of the extremities occurring in early life are a sign of a weak constitution, according to Dr. B. W. Richardson.

The Antagonism of the German and French Physicians.—The principal criticism I would make of the work the Germans are doing in this subject (bacteriology) is one which doubtless has presented itself to every medical man staying in Berlin. I refer to the jealousy exhibited toward Pasteur and the French school. I think this is carried so far that the Germans refuse to make use

of any method originating with the French (no matter how meritable such may be), for apparently no other reason than because it is of French origin. To be sure, this feeling may be, and probably is, reciprocal on the part of the French, and, if so, the old adage, "Two wrongs never make one right," applies here with much force. It is, indeed, lamentable that such conditions exist between two such renowned schools, as the profession (and I might add humanity) at large can but be more or less the losers by such a spirit of antagonism.—*Berlin Letter, Post-Graduate.*

The Pauper Insane.—The New York State Commission in Lunacy, since the passage of the State Care act, April 15th last, has transferred all of the insane poor of the following named counties to the State hospitals: Chenango, Clinton, Cortland, St. Lawrence, Saratoga, Schenectady, Schoharie, Sullivan, and Warren. Twenty-two counties have now no insane poor in their poorhouses or county asylums. Before the Legislature meets, by the foregoing transfers, discharges by judges, deaths, etc., of insane in county asylums and poorhouses, the number will have been reduced from 2,200 to 1,600. With the provisions which can be made under existing appropriations, and by reason of discharges by judges, deaths, etc., the number of insane patients in county asylums and poorhouses to be provided for on the 1st of May, 1891, will not exceed 1,200.

A Medical College Endowed by a Physician.—The Cooper Medical College, of San Francisco, which has recently completed its new building, has a somewhat unique history, for it has been built up and endowed by the savings and generosity of a physician, Dr. L. C. Lane. The college has one of the finest buildings for its purpose in the country, and has property amounting to a quarter of a million. This has come to it not through the patronage of multiple millionaires, but through the labors and savings of a physician.

The Trouble with the German Professor.—It may be observed, on occasions of a festive character, that the only trouble with the German socially is that he cannot cross his legs. Social intercourse can never reach its best, highest, and sincerest expression without a capacity for this anatomical position. In action the legs are parallel, in emotion they assume various expressive attitudes; but in the calm enjoyment of social life and supreme good-fellowship, they are crossed. Whether this physiological incapacity of the German is due to an absence of cortical areas for the adductors, or to peripheral neural weakness, or simply to an excessive intra-crural panniculus adiposus, I cannot say; but it is a racial defect that is deep-seated and pathetic.—*Post Graduate.*

Mortality in European Armies.—Recent statistics relative to the mortality among European troops in time of peace show that the Spanish army occupies the place of dishonor in this particular, with a death-rate of 13 per mille. Russia comes next with one of 9, then Italy with one of 7.74. Next in order come Austria with a mortality of, in round numbers, 7 in the thousand; France with 6, England with a little over 5, Belgium with a little over 4, and Germany with a little over 4. Consumption is rifest among English soldiers, and least prevalent among the French.

INOCULATIONS OF KOCH LYMPH IN NEW YORK.

In continuing, from our last issue, our report of inoculations in New York we append the following data obtained from original sources.

CASES AT ST. LUKE'S HOSPITAL.

Service of Dr. F. P. Kinnicutt.

Up to the present date fifteen patients, suffering from various forms of tubercular diseases, have been inoculated by Dr. Kinnicutt with Koch's lymph in the wards of St. Luke's Hospital.

The cases were carefully selected, with the view of thoroughly studying this method of treatment. All of them will remain under his personal observation in the hospital during the entire period of treatment, and a detailed report of their histories subsequent to inoculation will be published from time to time.

Two cases of lupus of the face, one case of lupus of the hand, accompanied by tuberculous infiltration of a limited portion of one lung; two cases of tuberculous glands (cervical); three cases of hip-joint disease with intermittently discharging sinuses; one case of tuberculous disease of tibia and fibula with open sinus; one case of prostatic surface tubercular disease; four cases of pulmonary tuberculosis in its first stage and limited in area; one case of doubtful diagnosis, are embraced in the above group.

Quantity of Lymph Used.—Thus far 0.001 gm. of the lymph has been used for the initial inoculation in all adult cases, and 0.005 in children.

Decided reactions have been obtained in all patients but one of the fifteen inoculated. The reactions have varied in the time of their appearance from four hours after inoculation to twenty-four; also in their intensity and duration.

Reactions.—The longest duration of the reaction has been forty-six hours. The highest temperature recorded during the reaction has been 104°. The increase in pulse and respiration rate has been proportionate to the rise in temperature. The local changes in the cases of lupus have corresponded very exactly with those recorded by the Berlin observers, and have been of the greatest interest. The differential diagnosis in the doubtful case mentioned, lay between lupus of the throat and tertiary specific lesion. No reaction followed the inoculation of 0.001 gm., and a second of 0.002 gm., and the case was accordingly regarded as one of specific disease.

No symptoms which could occasion any apprehension have been observed in any of the cases.

Tables are appended showing the symptoms and signs observed, during and following the inoculations, in three patients presenting different forms of tubercular disease.

Case I. *Phthisis.*—Female, aged forty. Tubercular infiltration of apex of right lung. Sputa contain very numerous tubercle bacilli. No rise of morning or evening temperature during the two weeks previous to inoculation. General condition good.

First inoculation, December 10th, 11 A.M., 0.001 gm. Reaction developed five hours after inoculation, slight chilliness, headache, general malaise, fever. Duration of reaction, twenty-one hours. Highest temperature, 101.2° F. Amount of sputa for twenty-four hours preceding inoculation, 11 drachms; for twenty-four hours following inoculation, 13 drachms; for second twenty-four hours following inoculation, 18 drachms; for third twenty-four hours following inoculation, 3 ounces. Urinary examination, a trace of albumin present before and after inoculation. Physical signs: Crepitation over affected area more marked, with numerous râles in larger tubes of same. No enlargement of spleen.

Second inoculation, December 13th, 3 P.M., 0.001 gm. Reaction developed thirteen hours after inoculation. Duration of reaction, nineteen hours. Highest temper-

ature, 101.2° F., seven hours after beginning of reaction. Amount of sputa for twenty-four hours following inoculation, 3 ounces. Urinary examination, trace of albumin, otherwise negative. Physical signs: Bronchial element of respiratory murmur distinctly more marked, and physical signs of infiltration obtained over an increased area. No enlargement of spleen.

Third inoculation, December 16th, 3 P.M., 0.001 gm. Reaction developed six hours later; chilliness, nausea, and fever. Duration of reaction, thirty hours. Highest temperature, 103.8° F., eighteen hours after inoculation. Amount of sputa, two ounces. Physical signs: Numerous moist râles in large tubes of affected area, abundant subcrepitation. No enlargement of spleen.

CASE II. *Prostatic Surface Tubercular Disease.*—First inoculation, December 11th, 3.30 P.M., 0.001 gm. Temperature normal. Reaction developed seven and a half hours later; rigors, headache, pains in limbs, general malaise, fever. Duration of reaction three hours. Highest temperature, 104° F. Local symptoms, pain and uneasiness over region of bladder, increased irritability of same. Urinary examination, small amount of albumin present before inoculation distinctly increased during reaction.

Second inoculation, December 13th, 3.30 P.M., 0.001 gm. Reaction developed four hours later. Duration of reaction, thirty hours. Highest temperature, 101½° F. Local symptoms similar to those following first inoculation. Urinary examination same as above, with a few hyaline casts. Physical signs:

Third inoculation, December 16th, 3.30 P.M., 0.001 gm. Reaction developed five hours later; rigors, headache and fever. Duration of reaction, twenty-nine hours. Highest temperature, 103.8° F. Physical signs: Severe pain felt at base of penis. Great irritability of bladder, the urine being ejected every fifteen or twenty minutes through supra-pubic opening.[1]

CASE III. *Lupus of Ear and Contiguous Portions of Face and Neck, of Twelve Years' Duration.*—Female, aged twenty two. Under treatment for the greater portion of this time. First inoculation, December 11th, 3 P.M., 0.001 gm. Temperature normal. Reaction developed, nine hours later. Slight rise of temperature and burning sensation in affected ear. Duration of reaction, twenty one hours. Highest temperature, 99.8° F. Local signs described in appended notes. Urinary examination negative. Physical signs, no enlargement of spleen.

Second inoculation, December 13th, 0.002 gm. Reaction developed eleven hours later; slight fever, decided burning sensation in affected ear. Duration of reaction, twenty-two hours. Highest temperature, 100.6° F. Local signs described elsewhere. Urinary examination, trace of albumin, otherwise negative. Physical signs negative. No enlargement of spleen.

Third inoculation, December 16th; 0.003 gm. Reaction developed six hours later; nausea, headache, chilliness, and fever. Duration of reaction, thirty hours. Highest temperature, 103.8° F. Local signs: more or less sero purulent exudation which crusts rapidly; crusts cover nearly the entire affected area. Hyperæmic areola, more than an inch in width, surrounds the entire patch. Posterior margin of patch presents a raw fissure as if the morbid tissue were separating from the healthy skin.

The local changes observed in the case of lupus are described as follows by Dr. George H. Fox, by whom the patient was referred to me.

Notes by Dr. George H. Fox of Case III., Lupus Vulgaris of Left Ear.—On December 11th, at 3 P.M. (date of first injection of lymph), the case presented the following appearance:

The left auricle was considerably thickened, of a dull red hue, and partly covered by adherent flakes of dead epidermis. Below the ear was a rounded, circumscribed patch of lupus, about the size of a silver dollar, the smooth surface of which presented well-marked cicatricial lines, the result of previous scarification. This patch extended for a short distance up behind the ear. Between the lines, the dull-red hue of the lupus tissue was still apparent. During the patient's two weeks residence in St. Luke's Hospital there had been no sensation of pain, burning, or itching in the affected part. On December 12th, 3 P.M., there was so marked a change in the apppearance of the ear, that it was noticeable at first glance, even at a distance.

The affected part appeared as though it were acutely inflamed or erysipelatous. The auricle had assumed a brighter red hue and was considerably swollen. The patch beneath and behind the ear was notably elevated, and the redness had increased to such an extent that the cicatricial appearance of the surface was no longer apparent. At the margin of the patch there was a narrow zone of hyperæmia, and a number of prominent red points which had not been noted on the preceding day, and which doubtless indicated the most recent infiltration of the healthy tissue. The patient stated that a burning sensation had occurred during the previous night, and the ear had felt quite painful toward morning. It now felt as it looked, swollen and inflamed.

On December 13th, the elevation of the patch and swelling of the auricle had subsided, and the color was less inflammatory. The burning sensation had gone. The epidermic flakes, especially upon the helix of the ear, were dry and whitish. At a single point on the patch below the ear, a serous exudation was noted. A second injection of the lymph was made.

On December 14th, there was not much change in the affected part. There was a slight increase of inflammation, but by no means so marked as after the first injection, although double the dose had been employed. There was no elevation of the margin of the patch, and the lobe of the ear felt a trifle softer. Below and behind the ear there was a slight moist discharge, with a tendency to honey-like crusting.

The patient stated that during the previous night she experienced "a heavy, stupid, sick feeling," and felt a sharp pain in the ear, as after the first injection, but the sensation of burning and swelling was much less this time.

On December 15th it was simply noted that the surface of the affected part presented more of an eczematous appearance.

The diagnosis of tubercular disease of the prostate in Case II. was made by Dr. Keys, by whom the patient was referred to me. The reaction obtained would seem to be corroborative of this diagnosis.

[1] Made previous to admission.

CASES AT MOUNT SINAI HOSPITAL.

Services of DRS. A. JACOBI and HENRY N. HEINEMAN.

CASE I. *Phthisis.*—Abraham K——, aged twenty-four, tailor, Russia; November 11, 1890. Family history negative. Present illness began five and a half weeks ago. After catching cold was seized with a fit of coughing accompanied by hæmoptysis. Following day sputum streaked with blood. Coughs most toward morning. Expectoration thick and yellow. Dyspnœa, hectic, night sweats, and pain in left side.

Physical Examination: Anterior right lung, slight dulness at apex, broncho-vesicular breathing, slight depression above clavicle; posterior right lung, slight dulness, prolonged expiration; anterior left lung, noisy inspiratory murmur, vocal resonance normal; posterior left lung, dulness over lower half of interscapular region, slight diminution of respiratory murmur over area of dulness, few slight subcrepitant bronchial râles in upper lobe occasionally.

First inoculation, December 11th, 0.000⅔ c.c.; second, December 12th, 0.002 c.c.; third, December 13th, 0.003 c.c.; fourth, December 15th, 0.004 c.c.; fifth, December 17th, 0.005 c.c.

Temperature usually but slightly elevated, never above 101° F. General slight reaction after first three doses. After fourth inoculation had intense headache and excessive vomiting. Cough and expectoration were increased by first inoculation. Spleen five inches by four inches.

CASE II. *Lupus.*—Franz D——, aged twenty-three, coppersmith, German, admitted December 4, 1890. Both parents died of phthisis. When five years old remembers a small patch opposite articulation of left inferior maxilla continuing for two years. In 1879, took rapid progress, spreading greatly, and has continued to increase. Has been scraped and cauterized. For past two and a half years no treatment. At present there is induration of deeper skin and nodules. Largest measurement 5 inches, shortest 1 inch, widest 3 inches. Superficial integument completely destroyed, surface red here and there, small crusts.

Inoculations: December 10th to 17th, six inoculations, up to 0.005 c.c. Within four hours after the first inoculation the lupus became red and swollen, remaining so for twenty-four hours, with an itching sensation. Within two days marked lessening in the induration was noted. Small red-brown spots along the anterior border after being redder became paler, and were finally covered with superficial extensive scales. The redness and swelling followed each inoculation, only to subside again. The temperature was not above 100° F., usually only 99° F. Moderate constitutional symptoms were complained of. Now the induration of cheek is gone; new nodules, not at first apparent, became so, then increased in size, then disappeared.

CASE III. *Phthisis.*—Edward S——, aged nineteen, cloak-cutter, United States. Admitted October 10, 1890. Family history: mother died of diabetes; one sister, chronic bronchitis. Caught cold after a Russian bath seven weeks ago, and three days later, in a severe coughing spell, was seized with hæmoptysis. Next morning had a second attack. Then had blood-stained sputum for two or three weeks, and a third hemorrhage a few days ago. Coughed day and night. Hectic at times. No night-sweats or diarrhœa. Has lost flesh and strength.

Inoculations: From December 10th to 17th had six inoculations, from 0.000$\frac{3}{5}$ c.c. to 0.004 c.c. Save the general malaise and headache, and moderately elevated temperature, together with slight chill, had increased cough.

Appears slightly improved in general appearance.

CASE IV. *Phthisis.*—Edward W——, aged twenty, clerk, Germany. Admitted October 26, 1890. Family history negative. Dyspnœa for past twenty-nine hours; an inclination to cough, with scanty sputum. Two months ago had hæmoptysis, nearly one-half pint. This was repeated nightly for two weeks. Has steadily emaciated, severe dyspnœa upon exertion. Cough mostly on rising. On admission patient was pale and anæmic; pulse, 115; respiration, 21; evening temperature, 102.4° F. in axilla.

Physical examination: Anterior left apex, dulness, bronchial breathing, moist râles; right apex, exaggerated breathing; posterior left apex, flatness, bronchial breathing; crepitant, subcrepitant, and mucous râles. Left base, breathing absent, fremitus transmitted; right base, exaggerated, high-pitched at apex.

Inoculations: Has received six inoculations from 0.00$\frac{3}{5}$ to 0.005 c.c., with moderate rise of temperature to 101° F., and save increase of cough and expectoration, the latter more diffluent, had only slight reactionary symptoms.

Although in a markedly cachectic state at the outset, he is, if anything, in slightly better general condition, otherwise the results are negative.

CASE V. *Lupus.*—Solomon G——, aged twenty, capmaker, Russia; admitted November 23, 1890. Mother died of phthisis. Father has phthisis. For five years has noticed redness of penis. Three months ago this began to ulcerate. Now (November 30th) the lower half of penis and overlying foreskin are involved in the growth. A ∧-shaped piece of glans penis, involving floor of urethra is destroyed. The glans on either side is ulcerated. Meatus and lower third of foreskin surrounded and penetrated by small nodules, and are much ulcerated; beneath the ulcer is a hard, indurated base.

Inoculations: From December 10th to 17th, has had six inoculations from 0.00$\frac{3}{5}$ to 0.004 c.c. From the outset the lupus became reddened within a few hours after the original inoculation. Steadily the redness has been followed by swelling which would subside, and with it a portion of the indurated base would melt away. This has been accompanied by itching in the parts and superficial scaling. The lupus has healed over one-third its area. The general symptoms have been malaise, headache, and those above noted, the temperature rising to 103° F. and over.

CASE VI. *Phthisis.*—J. R——, aged eighteen, cigarmaker, Russia. Admitted October 1, 1890. Father died of phthisis. Ten days ago seized with chilly sensations, cough and dyspnœa, and pain under the left nipple; thick greenish expectoration. Fairly well nourished. Pulse, 88; respirations, 28; temperature, 100.2° F.

Physical Examination: Dulness at left apex; bronchial voice and breathing from apex to cardiac area; posterior, left side, dulness at apex; bronchial vesicular breathing at angle of scapula. At right apex, bronchial voice and breathing; at angle, few fine subcrepitant râles.

Inoculations: First, December 13th, 0.002 c.c.; second, December 14th, 0.003 c.c.; third, December 15th, 0.004 c.c.; fourth, December 16th, 0.005 c.c.

Complains of yawning and restlessness. Had but slight cough previous to inoculation; this was much increased, as was the expectoration. Complained of intense pain over apex of left lung, the seat of disease.

Slight general malaise. Temperature usually normal, rarely 101° F.

CASE VII. *Tubercular Caries.*—Annie S——, aged seventeen years, single, Germany. Admitted June 22, 1890. Six years ago had ulcer on left side of face, another on abdomen, and a sinus over right big toe. Bones of toe removed. Removal since then of metacarpal bone of left finger. Caries of left tarsal bones and operation.

Condition December 10th fairly good; good appetite, well nourished; temperature has been normal for some months. Now has two sinuses over left foot.

Inoculations: December 11th, 0.002 c.c.; December 12th, 0.003 c.c.; December 14th, 0.004 c.c.; December 16th, 0.005 c.c. After first injections highest temperature was under 101° F.; after third and fourth the temperature rose to 102°+F. Besides headache, malaise, temporary loss of appetite, backache, after the last injection had pain and peculiar sensation in sore foot, and marked splenic and hepatic discomfort, and spleen decidedly enlarged. Still, further discharge from foot diminished.

CASE VIII. *Tubercular Joint.*—Daniel S——, aged fifty-three, married, Germany. Admitted November 6, 1890. Four months ago operated upon for exsection of ankle-joint, since then has had sinuses of left tarsus. Now pale, poorly nourished. Temperature before inoculation normal; appetite good.

Inoculations: December 12th received inoculation of 0.002 c.c.; December 14th, 0.003 c.c.; December 16th, 0.006 c.c. Nine hours after the first inoculation temperature was 101.6° F.; four hours after the second 100.6° F., and twenty-four hours after the third, 101° F. Beyond slight impairment of appetite and general malaise had pain in right hand and a slight papular eruption over abdomen December 13th, twenty-four hours after first injection.

CASE IX. *Tuberculous Glands.*—Leah F——, aged eleven, United States. Admitted November 7, 1890. For five or six years has had repeated operations for tu-

berculous glands and skin disease. Over right scapula old cicatrix of former disease. For some time cervical glands on both sides have been seat of ulceration and breaking down, involving the skin. Temperature normal to time of inoculation. December 9th, appetite good, bowels regular, fairly nourished, cheerful, no pain.

Inoculations: First inoculation, December 10th, 0.001 c.c.; second inoculation, December 12th, 0.002 c.c.; third inoculation, December 13th, 0.002 c.c.; fourth inoculation, December 16th, 0.003 c.c. Eleven hours after first injection temperature rose to 103° + F.; seven hours later cervical glands were markedly swollen. At the end of three hours more the swelling began to subside, and not until next day were glands as before. After second injection temperature did not rise above 100.8° F., and glands were only slightly affected. After third injection, in eight hours temperature had risen to 103.6° F., and in twelve hours more glands were again swollen. Child had general reaction after each injection, malaise, headache, impaired appetite, coated tongue with red edges, enlarged spleen, backache, etc. The reaction lasted two days, when the temperature became subnormal, 96.4° F. After the fourth inoculation the temperature in twelve hours was 105° F., and the patient had cold extremities, and was in a much depressed condition from which she rallied in six or eight hours. Glands swollen as before.

Case X. *Multiple Sarcomata.*—Lewis G——, aged forty, married, Russia, tailor. Admitted November 19, 1890. Was perfectly well up to last April, then began to have enlarged cervical glands. Was operated upon one month ago for enlarged cervical glands. Since then glands have reappeared upon both sides of neck and in both groins. Upon both sides of neck has an enormous chain of glands forming a continuous mass extending down into the mediastinum and with the trachea and thyroid making one large tumor.

December 10th.—Since admission glands have increased in size. Axillary glands involved, inguinal glands, and tumors appearing upon the right side, taking origin from periosteum of the ribs. Temperature only once has reached 101° F. Diagnosis, multiple sarcomata.

Inoculations: December 11th, 4 P.M., injection of 0.002 c.c. 5 P.M: pulse, 112; respiration, 24; temperature, 101.8° F. 8 P.M: pulse, 108; respiration, 24; temperature, 102.8° F. Feels as though something were running under skin of both hands and in glands of left side of neck. Next morning usual symptoms of infectious fever. December 12th, 3 P.M., injection, 0.002 c.c. Nine hours later, temperature, 102.8° F. Has pain in left hand. December 13th, second injection of 0.002 c.c.; December 14th, 0.003 c.c.; and December 16th, 0.004 c.c. The highest temperature was usually 102° F. and nine hours after inoculation he had the general symptoms of malaise, headache, slight loss of appetite, and peculiar sense of decided heat over left cervical region.

Case XI. *Lupus.*—Bertha B——, aged thirty-three, female, Germany, governess. Admitted December 13, 1890. Mother died of phthisis; both grandparents of cancer. Three years ago first noticed a small pimple of left labia of vagina; three months later it appeared upon right side, then both became confluent, broke down, and presented an ulcerating surface which presented the usual appearance of lupus. Eight months later she was first operated upon, since then has been repeatedly cauterized, and the tissues scraped out.

December 13th.—Upon admission, on each side of fourchette slight ulceration, in healthy condition, surrounded by no inflammation, tissue presenting no discharge. Ulcer on left side larger, possibly one-fourth greater in diameter, and both apparently of some depth. Upper end of ulcer overlapping lower. Beneath the ulcer, upon the left side, small indurated nodule.

Inoculations: First inoculation, December 13th, 0.001 c.c.; second inoculation, December 15th, 0.002 c.c.; third inoculation, December 16th, 0.003 c.c. But little constitutional reaction, save slight headache at times, and itching in seat of lupoid tissue, particularly upon left side. Examination, December 16th, shows diminution in size of ulcer upon left side.

Case XII. *Tubercular Caries.*—Bertha B——, aged fourteen, United States. Admitted December 8, 1890. Father died of phthisis. Five years ago was in German Hospital for eighteen months, repeatedly operated upon for carious bone. Her entire trouble dates back nine years, and is attributed to fall. Upon admission to hospital has a discharging sinus upon outer side of left thigh, left groin, and inflamed area over left wrist and over dorsal spine. Is markedly emaciated and anæmic, with poor appetite and normal temperature.

Inoculations: First Inoculation, December 14th, 0.0005 c.c.; second, December 16th, 0.001 c.c. No reaction save slight headache, and sweating.

Case XIII. *Tubercular Caries.*—Fannie L——, aged seventeen, tailoress, single. Admitted February 15, 1890. Has had carious bone disease for some years; was operated upon March 3, 1890, and again April 3, 1890, resection of knee-joint. Now fairly nourished. Has three sinuses about knee-joint leading to carious bone on lower end of femur. Appetite good. Temperature normal for a long time. Moderate discharge from sinuses.

Inoculations: First inoculation, December 12th, 0.002 c.c.; second, December 14th, 0.003 c.c.; third, December 15th, 0.004 c.c.; fourth, December 16th, 0.005 c.c. Discharge is less since last inoculation, otherwise the general reactive symptoms, the highest temperature being 101.6° F.

Case XIV. *Tubercular Caries.*—Charles M——, aged fifteen, Germany. Admitted December 3, 1890. Family history negative. Illness dates back five years. Repeatedly operated on for caries of right tibia. Latterly caries of rib; was operated upon, and one rib excised to extent of four inches—a portion of carious rib still left. General condition fairly nourished, pale and anæmic. Prior to December 11, 1890, had occasional evening temperature of 101° F., but usually only for a short time.

Inoculations: First inoculation, December 11th, 0.001 c.c.; second, December 12th, 0.001½ c.c.; third, December 13th, 0.002 c.c.; fourth, December 14th, 0.003 c.c.; fifth, December 16th, 0.004 c.c. Discharge diminishing from right carious rib; highest temperature, 101.8° F.; general symptoms of reaction moderate.

Case XV. *Tubercular Caries.*—Ida S——, aged twenty-one, married, Russia. Admitted December 13, 1890. For past nine months has been repeatedly operated upon for caries of left tarsus. Patient is now pregnant; has numerous sinuses over left tarsus. Is in general good condition. Temperature upon admission 99.8° F.

Inoculations: First inoculation, December 14th, 0.0005, c.c.; second, December 15th, 0.001, c.c.; third, December 16th, 0.002, c.c.; fourth, December 17th, 0.003 c.c. Except for pain in left foot, very slight reaction. Temperature normal most of time. Reached 102° F. once for short time.

Case XVI. *Lupus.*—Louisa S——, aged twenty, single, Germany; admitted December 14, 1890. Family history negative. Eighteen years ago had a few eruptive spots on left leg, upon right side of face, then upon right hand. Was operated upon three times, the lupoid tissue upon leg and face was destroyed. That on back of right hand has continued growing, involving back of middle finger for upper two joints, a small portion of upper joint of ring finger, and the immediately adjacent portion of dorsum of hand for a space of two by three inches. Portion over middle finger had thickly indurated base and also above it upon dorsum of hand. Upon the inner side of right arm she has three or four circular patches of three years' standing, which, at time of admission were pale, showing only superficial destruction.

Inoculations: First inoculation, December 15th, 0.001 c.c.; second inoculation, December 17th, 0.002 c.c. Eighteen hours after first injection temperature had risen to 102.8° F. Within eleven hours after first injection lupoid tissue became markedly red and swollen and the spots upon the inner side of the right arm became red and apparent. December 17th, it was noted that the lupus was covered with extensive scales and a slight diminution in induration is apparent.

CASE XVII. *Phthisis.*—Annie C——, aged nineteen, Russia; admitted December 7, 1890. Family history negative. Present illness dates back eight months. At that time had influenza. On admission to hospital was suffering with cough and muco-purulent expectoration, and had had slight hemorrhage, with pain in chest and back. Pulse, 94; respirations, 26; temperature, 98° F. Physical examination indicated incipient phthisis; posterior right apex, slight dulness; exaggerated voice and prolonged expiration.

Inoculations: From December 11th to 17th has had six inoculations, from 0.00⅔ to 0.005 c.c. Has had very little reaction. Face has been puffy; pain in inguinal regions, backache, headache, nausea, increased cough; spleen much increased in size.

CASE XVIII. *Phthisis.*—Dawson H. C——, aged thirty-three, United States; admitted December 14, 1890. Family history: Father and mother both living; one brother died of phthisis. Present illness dates back about four and a half years; then had slight cough with mucous expectoration. In March, 1886, had sudden hæmoptysis while sleeping, followed by a second hemorrhage two months later. Has had night-sweats and emaciation for past ten months.

Inoculations: First inoculation, December 15th, 0.001 c.c.; second, December 16th, 0.002 c.c.; third, December 17th, 0.003 c.c. Patient entered with temperature of 103° F. Since inoculations only once has his temperature touched 103° F., being generally lower. Says his cough is looser, and he feels bright; thinks he is slightly better. Slight reaction symptoms.

CASE XIX. *Phthisis.*—E. A. G——, aged fifty-five, United States; admitted December 11, 1890. Family history: Mother died of phthisis. Has one sister with lung trouble. Present illness dates back five years. At that time complained of sore-throat, and slight cough and hoarseness. Had slight hæmoptysis. Cough gradually became worse, with pain in chest, night-sweats, loss of flesh and strength, blood-stained sputum and diarrhœa. On admission to hospital, rather anæmic; pulse, 104; respirations, 40; temperature, 98.6° F. Physical examination indicates fibrous phthisis with small cavities. Dulness at both apices, anterior. On right, broncho-cavernous breathing, bronchophony, and pectoriloquy, gurgles, and pleural frictions; at left apex, bronchial breathing, increased voice, and pleural frictions; posterior, marked dulness at right apex, broncho-cavernous breathing, bronchophony, and pectoriloquy, pleural râles. Left apex same as in front. At right base, posterior, absent breathing and scattered subcrepitant râles.

From December 12th to December 17th has had five inoculations from 0.002 c.c. to 0.005 c.c., without any reaction or change whatsoever, save the usual symptoms of malaise, etc., but no rise of temperature.

CASE XX. *Phthisis.*—Captain T. A—— aged twenty-nine, Newfoundland, admitted December 11, 1890, family history negative. Has been an inveterate cigarette smoker. Present illness dates back two years; was exposed to wet and cold at sea. Some time later began to cough mucous expectoration. Has never had pain, but has been troubled somewhat with night-sweats. No hæmoptyses. On admission, condition good; physical examination indicates incipient phthisis, dulness at right apex with few fine râles and diminished breathing. At left apex, hyperresonance and prolonged expiration.

Inoculations: From December 12th to 17th, had five inoculations, up to 0.005 c.c. Cough and expectoration have increased, has had chills, temperature usually normal, and not over 100.2° F. Has had usual reaction symptoms, headache, malaise, splenic and liver discomfort and engorgement. Thinks to-day he feels better, though he has complained of weakness before.

CASE XXI. *Phthisis.*—Baerman W——, aged twenty-two, Roumania, admitted December, 1890. Family history negative. Illness dates back six months, with pain in chest and back. Has had cough for three months, with mucous expectoration. No hemorrhages. On admission to hospital was in fairly good condition. Pulse, 96; respiration, 24; temperature, 98.8° F. Physical examination indicates beginning phthisis. Dulness at both apices. Broncho-vesicular breathing at left; pleural râles.

Inoculations: First inoculation, December 13th, 0.002 c.c.; second, December 14th, 0.003 c.c.; third, December 16th, 0.004 c.c. Ten hours after second inoculation, temperature rose to 104° F. After third inoculation highest temperature was 102.2° F. Otherwise, had chill, malaise, etc., increase of cough and expectoration.

CASE XXII. *Empyæma.*—Charles M——, aged twenty-seven, Germany, admitted December 1, 1890. Family history negative. Present illness dates back two weeks, when patient caught severe cold. Had chill, headache, considerable cough, but no expectoration. Also complained of pain in left side, with some dyspnœa. On admission, condition good. Pulse, 124; respiration, 24; temperature, 100° F. Physical examination and aspiration indicate empyæma. Signs of fluid in pleural cavity.

Inoculations: Three injections, one of 0.00⅔ c.c.; a second of 0.001 c.c.; and a third of 0.002 c.c. were given, and followed by high febrile reaction, vomiting, headache; a severe chill following within twenty minutes of first inoculation.

CASE XXIII. *Phthisis.*—Max F——, aged thirty-four, Germany, salesman, admitted December 3, 1890. Family history—father died of cancer, and mother in childbirth. Present illness is of six months standing. Began with vomiting, pain in throat, and cough with muco-purulent expectoration. Has had several hæmoptyses, sweats at night. Has dyspnœa on exertion, and has lost flesh and strength. On admission, well nourished. Pulse, 124; respiration, 32; temperature, 99° F. Physical examination, beginning phthisis, dulness at left apex in front, and at both apices posteriorly, broncho-vesicular breathing, and pleural râles. Has aphonia; tuberculous ulceration of both vocal cords.

Inoculations: First inoculation, December 12th, 0.002 c.c.; second inoculation, December 13th, 0.003 c.c.; third inoculation, December 15th, 0.003 c.c.; fourth inoculation, December 17th, 0.004 c.c. Temperature rose to 103.6° F. within an hour after first inoculation, and was normal in six hours. Four hours after second inoculation, rose to 103.2° F.; five hours after third inoculation, to 102.8° F. He has had inguinal pain, increase of cough and expectoration, less night-sweats. Has had the usual reaction symptoms; spleen has increased to four and one-half inches. Says upon the whole he feels better, and appears brighter. Voice slightly better.

CASE XXIV. *Phthisis.*—Julie N——, aged nineteen, housework, Austria. Admitted December 6, 1890. Family history, mother and sister died of phthisis. Present illness dates back seven months. Was taken with sudden hæmoptysis while at work, and on following day a second. Was in bed one week, during which time had a third hemorrhage. Complains of slight cough and pain in chest, and night-sweats. On admission, in fair condition.

Physical examination: Incipient phthisis, dulness at left apex, broncho-vesicular breathing, pleural friction sounds and subcrepitant râles.

Inoculations: From December 11th to December 17th received six inoculations from 0.000⅔ c.c., to 0.004 c.c. Only after 0.003 c.c. was inoculated did the temperature reach 102.6° F., the rise being before confined to 101.6° F. Her general condition has remained unchanged, cough is

more and expectoration increased. Besides this has had the general reaction symptoms of malaise, etc., to only a moderate extent.

Pott's Disease.—Harry B—, aged eighteen, carpenter. Admitted December 17, 1890. History of Pott's disease involving lumbar spine with pelvic abscess and sinuses in left lumbar region posteriorly, and iliac fossa anteriorly.

Inoculations: From December 10th to 17th, five inoculations up to 0.004 c.c. Save elevation in temperature below 102° F. and slight constitutional symptoms, no change in wounds.

CASES AT THE GERMAN HOSPITAL, NEW YORK, DECEMBER 17, 1890.

Service of A. JACOBI, M.D., and WILLY MEYER, M.D.

[Reported by A. MÜLLER, M.D., Assistant.]

CASE I. *Phthisis.*—Adam H——, aged thirty-nine, gardener; phthisis pulmonalis. History of one year's sickness: hæmoptysis four weeks ago; upper lobes of both lungs involved; large cavity on left side; sputum contains bacilli.

Inoculations: First inoculation, December 11th, 0.001 c.c.; second, December 12th, 0.002 c.c.; third, December 14th, 0.004 c.c.; fourth, December 15th, 0.004 c.c.; fifth, December 17th, 0.005 c.c. After first inoculation a sudden rise of temperature to 105° F., intense sweating, no chill. After fourth inoculation, cough looser, expectoration less like pus than before. Same rise of temperature after each inoculation. General condition good. Physical examination not changed.

CASE II. *Phthisis.*—Alos B——, aged thirty three, druggist; phthisis of one and a half year's standing. Both upper lobes involved; cavity right side; sputum contains tubercle bacilli.

Inoculations: First inoculation, December 11th, 0.001 c.c.; second, December 12th, 0.002 c.c.; third, December 13th, 0.003 c.c.; fourth, December 14th, c.c. 0.004; fifth, December 15th, 0.004 c.c.; sixth, December 16th, 0.005 c.c.; seventh, December 17th, 0.005 c.c. No reaction after first; slight rise of temperature (101.4° F.) several hours after third inoculation. Cough looser; expectoration in quantity not changed; its quality is less pus-like than before inoculation; no chills; no malaise; physical signs unchanged; bacilli found in yesterday's sputum; complaint of great pain at the point of inoculation; after third inoculation, slightly swollen, inflamed.

CASE III. *Phthisis.*—Hubert C—, aged nineteen, clerk. Incipient pulmonary phthisis. Ill since spring of 1890. Both apices slightly involved; no hæmoptysis; sputum contains bacilli.

Inoculation: December 15th, 0.002 c.c. No noticeable reaction.

CASE IV. *Phthisis.*—Moritz P——, aged twenty-one, tinsmith. History of nine months sickness; unable to take food for six weeks. Left upper lobe involved. Both true vocal cords are eroded. False vocal cords show superficial ulcerations. Posterior laryngeal wall is thickened. Bacilli in sputum.

Inoculations: First inoculation, December 13th, 0.001 c.c.; second, December 14th, 0.002 c.c.; third, December 16th, 0.004 c.c.; fourth, December 17th, not given. Large rise of temperature several hours after first inoculation (102.3° F.); after last inoculation patient complains of pain in throat and chest; coughs, expectorates very much more than usual; more infiltration of post-laryngeal walls.

CASE V. *Phthisis.*—Gustave P——, aged thirty-two, clerk. Ill since spring. Right apex slightly involved; symptoms and physical signs not very marked; bacilli present.

Inoculations: First inoculation, December 12th, 0.001 c.c.; second, December 13th, 0.002 c.c.; third, December 14th, 0.003 c.c.; fourth, December 15th, 0.004 c.c.; fifth, December 17th, 0.005 c.c. No noticeable reaction after first two inoculations. After the third patient complains of pain in left side of chest, above. After fourth inoculation, rise of temperature, several hours after (101.6° F.); no chill; cough and expectoration nominal.

CASE VI. *Tuberculous Disease of Knee-joint.*—Anna P——, aged nineteen, tuberculosis of right knee-joint. History of one year's duration.

Inoculations: First inoculation, December 13th, 0.001, c.c.; second, December 14th, 0.004 c.c.; third, December 15th, 0.004 c.c.; fourth, December 16th, 0.005 c.c. Marked pain in knee-joint after first inoculation, extending to hip-joint; slight rise of temperature, 100.6° F. After third inoculation decided diminution of size of affected knee-joint. Slight cough; anorexia.

CASE VII. *Tubercular Pelvic Abscess of Several Months' Standing.*—Jacob P——, aged five years.

Inoculations: First inoculation, December 13th, 0.001 c.c.; second, December 15th, 0.001 c.c.; third, December 17th, 0.002 c.c. Abscess healed, fistula remaining; diminution in secretion from fistula; pains at point of inoculation; sleeplessness; intermitting pulse; face pale, profuse perspiration; stertorous respiration; thirst; rise of temperature to 102° F. after first inoculation, twelve hours.

CASE VIII. *Lupus of Nose and Upper Lip and Left Cheek.*—Wilhelmine K——, aged nineteen. Family history tubercular. Patient sick eight years ago.

Inoculations: First inoculation December 11th, 0.001 c.c.; second, December 12th, 0.0025 c.c.; third, December 14th, 0.004 c.c.; fourth, December 16th, 0.005 c.c. First day, pain, swelling, hyperæmia of affected parts; spreading of inflammation to the left cheek. Second day: Appearance of pustules on nose and lip; redness disappears. Third day: During night sleepless; slight cough; no expectoration; pain in the chest, and at point of inoculation; itching of nose and lip; slight chill. Rise of temperature to 102.8° F. Fourth day: Marked anæmia of affected parts; skin shrivelled; nodules prominent. After this nothing special except slight rise of temperature after inoculations.

CASE IX. *Tubercular Prevertebral Abscess.*—Ida S——, aged sixteen. Eight months' duration; fistula present.

Inoculations: First inoculation, December 11th, 0.001 c.c.; second, December 12th, 0.002 c.c.; third, December 13th, 0.004 c.c.; fourth, December 14th, 0.004 c.c.; fifth, December 15th, 0.004 c.c.; sixth, December 17th, 0.005 c.c. After first inoculation, several hours, temperature 102.6° F. No other symptoms. Second inoculation, slight cough, sleeplessness; secretion diminished, less purulent; more serous. Third inoculation, profuse sweats; temperature up to 102.2° F. Fourth inoculation, moderate rise of temperature only. Fifth inoculation, moderate rise of temperature only. Otherwise no particular symptoms of change.

CASE X. *Tubercular Arthritis of Ankle.*—Augusta M——, aged three years. Ten months' duration; discharging fistula.

Inoculation: First inoculation, December 11th, 0.001 c.c.; second, December 12th, 0.00075 c.c.; third, December 13th, 0.0015 c.c.; fourth, December 15th, 0.001 c.c.; fifth, December 16th, 0.002. After first inoculation, rise of temperature to 104° F., eight hours after; chill none; respiration stertorous, loud; edges of wound reddened; diminished secretion. Second inoculation: Six hours after, temperature, 104° F.; marked somnolence; profuse sweating; dilated pupils. Third inoculation: Rise up to 101° F. only; secretion from fistula less bloody and less purulent; more serous and less in quantity. Fourth injection: Rise to 101.2° F.; wound pale; very slight serous discharge only; fistula seems to close up. Fifth injection: Rise during the night to 100.3° F.; nothing special noticed except spasmodic contractions of right side of neck and leg.

Besides these there were two patients inoculated

for suspected phthisis; quantity, 0.002 c.c.; and one case of suspected lupus, 0.001 c.c.; and one case of disease of elbow-joint (suspected tubercular), 0.001 c.c. These injections were made for the purpose of diagnosis. The case of elbow joint disease is proven to be tubercular.

CASES AT THE NEW YORK FOUNDLING ASYLUM.

Service of DR. A. JACOBI.

[Reported by DR. CLARK, House Physician.]

CASE I. *Tubercular Meningitis.*—Female, aged nineteen and a half months. Diagnosis, tubercular meningitis, advanced stage. At time of inoculation semi-comatose, respiration irregular and sighing, pulse very irregular and rapid, frequent convulsive movements of arms. Temperature varying from 100° to 102.2° F.; pulse, varying from 130 to 180; respirations, 16.

Inoculation: December 12th, 3.30 P.M., patient was inoculated beneath skin of abdomen with one half milligramme of Koch's lymph. The temperature, taken every hour, dropped slowly from 101.2° F. at 4 P.M. to 99.5° F. at 9 P.M. The pulse continued irregular, varying from 154 to 176. The respirations increased in number, and at 9 P.M. had become markedly more regular. After 9 P.M. there was a slight increase in temperature to about 100° F., at which it remained until 3 to 4 A.M., December 13th, when it rose one degree and fell again to 100° F. an hour later. At 10 A.M. the temperature rose again, reaching 102° F. at 4 P.M. The pulse increased in frequency during this time, reaching 190 in the early morning, but decreasing to about 160 in the afternoon. The respirations remained at about 28. The coma was, perhaps, slightly less marked, and the convulsive movements of the arms unchanged. There was no local reaction save a papule at site of inoculation, about one line in diameter.

December 13th, 4 P.M.—Inoculated under skin of abdomen with one milligr. of Koch's lymph. Temperature remained slightly above 102° F. until 2 A.M., December 14th, when it fell one-half a degree. The pulse and respirations remained the same. At 9 P.M. (Dec. 13th) the convulsive movements had become much more marked, the arms being raised to the sides of the head and above it. There was an occasional short cough. The child moaned frequently and was restless. During the morning of December 14th the convulsions became almost continuous, the arms being now held at or near the sides, forearms strongly supinated, hands flexed on wrists, fingers and thumbs flexed on palms. Abdomen somewhat distended. External strabismus marked, pupils contracted. Moaning louder and more frequently.

11 to 11.30.—Changed suddenly. Temperature, which at 10 A.M. had been 102.8° F., had now risen to 105° F., the pulse was 190–200, and the respirations 95–100. The convulsive movements stopped entirely.

The child sank slowly and died at 1 P.M.

CASE II. *Tubercular Abscess.*—Male; aged five years, eight months. Diagnosis, tubercular abscess discharging from sinus in right inguinal region, of five and one-half months' duration. Temperature generally normal, but with occasional accelerations. At time of inoculation temperature was 99.5° F.

December 13th.—Inoculated under skin of abdomen with one-half milligramme Koch's lymph. At midnight the child was wakeful and complained of pain at site of inoculation; this, however, was certainly not marked. The temperature did not begin to rise until between 2 and 4 A.M.

December 14th.—At 4, it was 101°, at 8 A.M., 102.2°, and at noon, 103° F. The pulse and respirations were also accelerated, the former reaching 156, the latter, 38. The temperature remained at 103° F. until between 4 and 6 P.M., when it began falling, but did not reach normal, 98.5°, until 6 A.M.

December 15th.—There was now noticeable a slight induration at site of inoculation, and a faint blush on the skin in this region. Pressure here gave pain. At 4 P.M., the temperature then being 99.2° F., pulse 132, and respirations 30, the patient was again inoculated beneath skin of abdomen with one-half milligramme of the lymph. At 8 P.M. the temperature had risen one degree, with corresponding rise in pulse-rate to 144. There was no further change until 4 A.M., December 16th, when the temperature had increased to 100.8° F. From this time it dropped, reaching 99° F. at 2 P.M. At 4 P.M. the patient was reinoculated with one milligramme of lymph, the dose being increased on account of the slight reaction which had followed previous injection. There were no further symptoms attributable to the effect of the lymph, save that from twelve to sixteen hours after the first inoculation the discharge from sinus was thought to have materially increased. It has since remained as usual.

CASE III. *Spinal Caries.*—Male, aged four years and nine months. Diagnosis, spinal caries; dorsal kyphosis of over two years' duration.

Inoculation, December 13th. Temperature at time of inoculation 99.2° F. At 4 P.M. patient was inoculated under skin of abdomen with half a milligramme of the lymph.

December 14th.—At 2 A.M. the temperature began to rise, reaching 102.5° F. at 4 A.M.; and 103° F. at 2 P.M., from which time it gradually declined to 99° F. at 10 P.M. During the elevation in temperature the pulse reached 156, and the respirations 42. Through the night of the 13th to 14th, the patient was somewhat restless but showed no further reaction.

December 15th.—In the morning some induration had appeared at site of inoculation, together with a faint pink blush on the skin at this place. At 4 P.M. inoculated under skin of abdomen with half a milligramme of lymph.

December 16th.—Temperature rose one and a half degree between 2 and 8 A.M. (*i.e.*, it reached 100° F.). There was also a slight rise in pulse and respiration rates. No further reaction. At 4 P.M. inoculated with one milligramme of lymph.

December 17th—At 4 A.M. the temperature had reached 100.5° F., the pulse 144, and the respiration 36. No further reaction.

CASE IV. *Acute Peritonitis of Left Tibia.*—Male, aged four years. Previous history: October, 1889, operation for acute periostitis of left tibia, lower third; sinus established three months later. November, 1890, sequestrotomy, lower third of left fibula, making good recovery. November, 1890, enlargement in region of, and above right knee, apparently not inflammatory; somewhat painful to touch. Enlargement of glands of right side of neck, non-inflammatory.

Inoculation: At time of inoculation temperature had been normal for two weeks.

December 13th, 4 P.M.—Inoculated with half a milligramme of lymph, beneath skin of abdomen.

December 14th.—Between 6 and 8 A.M., temperature began to rise, reaching 101.8° F. at 2 P.M., from which time it gradually declined to 98.5° F. at 12 M. Corresponding to the rise in temperature the pulse reached 144, and the respirations, 36. During the afternoon, there appeared some induration at site of inoculation with a slight reddening of the skin. Tongue lightly furred, reddened at tip and edges, papillæ prominent. No further reaction.

December 15th, 4 P.M.—Inoculated with half a milligramme of lymph.

December 16th.—Slight febrile reaction between 6 A.M. and 12 M. Temperature reached 100.5° F., pulse 138, and respirations, 32. There appeared, also, a fine, pale, papular rash over most of body, thickest on abdomen, thighs, and about neck. No further reaction.

4 P.M.: Inoculated with 1 milligramme of lymph.

December 17th, 8 A.M.—Temperature had reached 100.5° F., pulse, 134; respirations, 36. No further reaction.

CASE V. *Tuberculosis of Ankle.*—Female, aged five. Two years ago the left ankle was excised and bacilli found. One year ago, right hip-joint became diseased. Between seven and eight months ago a sinus was established at hip which has since been discharging. There has been, off and on, periods of considerable pyrexia, the last, about four weeks ago.

The temperature at time of inoculation was 101.5° F. This temperature is thought to be due to agitation on the part of the child, as it fell to 99.5° F. between two and three hours later.

Inoculation: December 13th, 4 P.M., inoculated with half a milligramme of lymph. December 14th at noon the temperature had reached 101.2° F.; pulse, 136; respiration, 36. From this, the temperature slowly declined to 99.5° F. at midnight. The discharge from sinus was thought to have increased considerably; it has since returned to its usual amount.

December 15th.—There is slight induration and some reddening of the skin at the site of inoculation. At 8 A.M. the temperature again began to rise, reaching 103° F. at noon. From this time it declined to 99° F. at 8 P.M.

4 P.M.: Inoculated with half a milligramme of lymph.

December 16th.—The temperature began rising at 2 A.M., and at 2 P.M. had reached 103.2° F., the pulse being 158 and the respiration 42.

4 P.M.: Inoculated with one milligramme of lymph.

December 17th.—Reaction comparatively slight. Highest temperature, 100.2° F. at 4 A.M. and 101.8° F. at noon; otherwise, the temperature has been below 100° F. The pulse reached 144 and respirations 36.

CASES AT THE POLYCLINIC HOSPITAL.

Service of DR. HEINEMAN.

DR. H. N. HEINEMAN has treated two cases of males, twenty and twenty-two years age, one with incipient phthisis, and the second with phthisis in second stage; having broncho-cavernous breathing at right apex and consolidation at left apex. The first gave ancestral history; the second, family history negative. Both have a history of one year's duration. The first has had repeated hemorrhages up to two months ago; the second has ulceration of vocal cords. In both cases two injections of 0.001 c.c. and 0.002 c.c. have been given.

Reaction moderate as to constitutional symptoms; temperature below 101° F.; spleen large in both cases. Cough increased in both. Moderate malaise and headache, splenic and hepatic discomfort.

Negative Results in Examination of Sputa.—Dr. T. Mitchell Prudden, of the Laboratory of the Alumni Association, College of Physicians and Surgeons, writes: "The variation in the number of tubercle bacilli in the sputa is often so considerable from day to day, under any treatment or no treatment of phthisis, that as yet the numbers found after the use of the lymph cannot be fairly considered as of especial significance. There is not sufficient data as yet for any conclusion."

At the St. Mark's Hospital.—Thirty injections were made by Dr. L. Weber upon seven patients during the past week. Only twice was there a high febrile reaction, amounting to 104⅘° F. In some patients a copious expectoration was noticed, which afterward decreased considerably and became less than it was previously. In one patient with a tuberculous ankle-joint, which had been previously resected by Dr. Beck, and in another who had suffered with enlarged cervical glands which had been extirpated, no local reaction was observed about the diseased surfaces.

The Lymph in New Haven.—The lupus cases for which lymph inoculation was made in New Haven, and previously reported, are said to be improving, and the examinations of the sputa in the tubercular cases show a progressive decrease of bacilli.

The Lymph in Philadelphia.—The first injections of the lymph made in Philadelphia by the University Commission were on the 17th, in the case of a patient suffering from tuberculosis of the knee-joint, and one from tuberculous phthisis. Professor J. William White was the operator. A patient with tubercular phthisis was also operated upon the same date at the Jefferson Medical College.

KOCH'S METHOD IN LONDON.

(From our Special Correspondent.)

LONDON, December 3, 1890.

Two public demonstrations of Koch's method have just been given in London. One of these was given on Monday evening, by Dr. Heron, at the City of London Hospital for Diseases of the Chest, Victoria Park; the other, at King's College Hospital, this morning, by Mr. Watson Cheyne, one of the surgeons to the hospital. I have attended both of these, so send these few notes by to-day's mail for the early information of your readers.

At Victoria Park Hospital the cases shown were those of patients suffering from pulmonary phthisis, with the exception of a few cases of cutaneous lupus kindly provided by Dr. Radcliffe Crocker, and admitted temporarily (for teaching purposes) into the wards of the Victoria Park Hospital. Dr. Heron's demonstration was given in one of the wards of the hospital, converted for the time being into a lecture-room; between one and two hundred medical men were present. Before showing any patients Dr. Heron gave a short address on the subject. He emphasized the importance of not being too sanguine as to the efficacy of the remedy in cases of pulmonary tuberculosis—at any rate in cases of advanced disease. Koch himself had at first only thought that it would be applicable to cases in which there was tubercular disease of glands, bones, or joints, or to cases of lupus of the skin. In cases of phthisis it could not be expected to be curative unless applied in the early stage. These limitations, said Dr. Heron, should be borne in mind. He had not, when in Berlin, seen enough of its action on advanced cases of phthisis to form any opinion himself as to its probable value in them.

A small bottle of the fluid was handed round for inspection. It was explained that two dilutions of it were in use, viz., a one per cent. solution and a ten per cent. solution. These were prepared from the original liquid by diluting it with distilled water; if the latter contained one-half per cent. of carbolic acid the resulting solution was less likely to undergo decomposition. Owing to the dilutions keeping badly they should be freshly prepared—say within a week of using them. One cubic centimètre of the one per cent. solution contained 0.01 c.c. of the remedy; this had been shown to be the smallest dose which produced any effect at all in a healthy adult. Tuberculous patients were more sensitive to the action of the remedy, and to them the initial dosage was usually 0.001 c.c. or 0.002 c.c. of the one per cent. solution. Dr. Heron observed that a somewhat different method was adopted in cases of lupus and in cases of phthisis. In the former, a full dose (0.01 c.c. of the one per cent. dilution) was administered, and a second injection not given for a week or more. In cases of lung disease small doses were given to begin with (0.001 or 0.002 c.c. of the one per cent. dilution) and repeated daily—the dose being gradually increased until it reached the same as that given to patients suffering from lupus. In either case the injections were continued until they failed to produce any

reaction. In early cases of phthisis the period of time necessary to obtain this result was about six weeks. The syringe employed—a description of which has already appeared in the MEDICAL RECORD—was passed round for examination.

Several cases were then exhibited, on whom the remedy had been tried. The first patient shown had been injected in the morning, and the reaction was at its height. The patient was a man suffering from early phthisis; his bed was carried into the ward in which the demonstration took place. In six hours his temperature had risen from 98° to 104° F., the pulse rate had increased from 90 to 148, and the respirations from 24 to 33 per minute. The rise of temperature had been preceded by a slight rigor. Eleven hours after the injection the temperature was 103.6° F. In most cases the temperature rose in from three to five hours after the injection and reached its highest point (which might be 106° F.) in from ten to twelve hours after the injection. Dr. Heron remarked that his experience was that shivering and nausea were by no means constant symptoms; in only one of his cases were rigors marked. Several other patients were then shown; most of these were cases of early phthisis, but a few were examples of lupus. Dr. Heron said that he had made it a rule not to inject any phthisical patient except those in whom bacilli had been proved to be present in the sputum. One patient he had injected as a control experiment, and the result was interesting. The case was that of a young woman, suffering from anæmia and amenorrhœa; breathing was not good, but there were no physical signs indicating tubercle. The second injection was followed by a marked reaction. The obvious inference was that tubercle was present, though I believe Dr. Heron did not state this inferenee in explicit terms. Two cases of lupus were shown. In one of these the reaction was at its height—the patient's temperature being elevated and the lupoid tissue red and swollen; in the other, sufficient time had elapsed since the last injection for the reaction to subside, and signs of amelioration were already present, as evidenced by comparing the condition of the patient with her appearance in a photograph taken before the commencement of treatment. The demonstration was terminated by injecting a few patients in the presence of the audience.

Mr. Watson Cheyne's demonstration was given this morning, in the operating theatre of King's College Hospital, which was crowded to its utmost capacity. Before having the patients brought in, Mr. Cheyne made a few prefatory observations. He was ignorant, he said, both of the composition of the remedy and of its method of preparation, and he had refrained from questioning Dr. Koch on the subject, as he did not wish to be the possessor of a secret which everybody thought he ought to have. Mr. Cheyne said there was no doubt that Dr. Koch would communicate his process in due time. There was no question of its being kept as a secret remedy, but at present there were difficulties in its preparation. The strength of different samples was found to vary, and every one had to be personally tested by Dr. Koch before being sent out. If the process were now revealed, the preparation would probably be manufactured on a large scale and in such a manner that satisfactory results would not be obtained, and, as a consequence, the remedy would fall into discredit. Dr. Koch was most anxious to avoid the latter result.

Mr. Cheyne said it was uncertain how the remedy acted, but he had himself constructed a working hypothesis, for which, however, he alone, and not Dr. Koch, was responsible. His hypothesis was as follows: Certain substances, he suggested, were produced by the bacilli, and to their irritant action was due the growth of tubercular tissue. (In the case of pyogenic organisms it was now, he said, admitted by bacteriologists that it was not to the organisms themselves but to their chemical products that suppuration was due.) Koch's remedy probably contained some substance which combined chemically with the bacillary products to form a fresh compound, which had extremely irritant qualities and produced destruction of tubercular tissue. On this hypothesis it was explicable how the action of the remedy was limited to tubercular tissue only. Mr. Cheyne said he did not wish to insist on the accuracy of his view, but it was necessary to have some such hypothesis in order to work with the remedy.

The theory put forward would suggest the desirability of only giving small doses in the case of tubercle of internal organs, as, for example, the kidney, where the resultant inflammation might have an ill effect; in tuberculosis of external parts larger doses might be ventured on. Mr. Cheyne observed that the remedy, whatever its nature, was evidently a powerful poison and should only be used with the greatest care.

A number of patients were then brought into the theatre. Several cases of lupus were shown. One of these had been operated on twenty-four times and the alæ of the nostrils were partly destroyed. Mr. Cheyne said that in this case it was inadvisable to give the full dose in consequence of the swelling of the nasal passages which would probably result. Several cases of disease of bones and joints were shown; in one of the latter no reaction had been produced, and the disease was therefore probably not tubercular. A young child was shown who had been operated on for encysted hydrocele, and on whom also circumcision had been performed before he left the hospital. Six weeks later the circumcision wound was unhealed, and (in Mr. Cheyne's opinion) had become tubercular. The old wound in the scrotum had reopened. One testis became tubercular and was removed. Mr. Cheyne determined to employ Koch's remedy. (The parents of the child had expressed a wish to take him to Berlin.) When shown this morning the child appeared very ill and much emaciated. The first injection was then made– only a small dose being given. A most interesting case was one of tubercle of the iris, which was brought in a cab from the Moorfields Ophthalmic Hospital to be injected. In this case Mr. Cheyne remarked that it would be unwise to provoke any considerable degree of inflammation, and he accordingly injected only one-tenth of a centimètre of the one per cent. dilution.

Intubation without Gag or Extractor.—Dr. Guido Bell, of Indianapolis (*Journal of the American Medical Association*), says that he has discarded both the gag and the extractor. The child being seated on an attendant's lap, he passes his left index-finger into the mouth and behind the root of the tongue. On this the little patient "gags," and the larynx rises to the operator's finger, when the tube is at once pushed into the larynx with the right hand and kept in place for a moment with the left. The thread is then fastened to the patient's cheek. The advantages of this method, according to Dr. Bell, are that no assistant is required, the child is not excited and does not dread a repetition of the operation, and the tissues of the pharynx and larynx are not injured by sudden movements of the patient. Dr. Bell states that the child's glottis gives to the finger much the same sensation as the os uteri. If it feels "smeary," the suffocation is said to be due to membrane rather than to œdema. Dr. Bell has intubated in the way described over a hundred times, and has been successful in introducing the tube at the first attempt except in two or three "asphyxiated cases." He removes the tube without an extractor by simply grasping the larynx externally with the fingers and pressing it out. Dr. Bell has done this in five cases in which removal with the extractor had completely failed. But his estimate of intubation is not very encouraging. He says it has not very much increased the percentage of recoveries in his practice, and most of the little patients have died. Perhaps Dr. Bell will improve his statistics by returning to the use of the gag and extractor.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, November 10, 1890.

ROBERT ABBE, M.D., CHAIRMAN.

Rupture of the Short Head of the Biceps Brachialis.—DR. V. P. GIBNEY presented a man, forty years of age, who had obtained excellent use of the arm after rupture of the short head of the biceps brachialis, which took place while lifting some object of weight. The only treatment which it had received was rest and the application of a bandage.

Epithelioma of the Nose; Plastic Operation.—DR. I. H. HANCE presented a woman who showed very good results from a plastic operation to repair the ravages of an epithelioma invading the nose.

Fracture of the Sternal End of the Clavicle.—DR. B. E. VAUGHAN presented a lad who had sustained a fracture of the clavicle in an unusual location, near the sternal end. A very fair result had been obtained by the use of strips of adhesive plaster and pads which exerted pressure.

DR. CHARLES A. POWERS showed photographs of a case which he had treated for fracture in the same location. The patient had previously been treated for a like fracture in the other clavicle, in London, which showed a greater amount of deformity.

Rupture from Trauma in Ectopic Gestation at about the Fifth Month; Laparotomy; Recovery.—DR. THOMAS H. MANLEY presented the fœtus, some clots, and the patient, in a case of ectopic gestation. The woman had fallen into a trench about nine days before she came under his care, and afterward suffered pain in the region of the lower abdomen. She had ceased to menstruate in April, some five months before, and had afterward shown the usual symptons of ordinary pregnancy. She had a flooding two days before he saw her, and an obstetrician supposed there had probably been an abortion. Dr. Manley found distinct signs of peritonitis, and in the left iliac fossa he felt a fulness. Supposing this might be pus, he recommended an incision. The patient was much exhausted, and it was a question whether she would survive. The next morning, in the presence of Dr. Malcolm McLean and others, he made a medium incision, came down upon a mass of blood-clots, and then upon a placenta, and after some search found the fœtus near the right kidney. The fœtus was about eight inches and a half in length, and evidently had reached the fifth month. The operation was one of the simplest which he had ever performed; there was very little hemorrhage; the woman made a very good recovery, and was present at the meeting.

The case was an extremely rare one. Dr. Thomas had stated that only two cases had been recorded in this country in which the woman had recovered after rupture from traumatism in ectopic gestation past the fourth month.

Hysterectomy for Interstitial Fibroid.—DR. MANLEY also presented a large fibroid mass, with the uterus attached, which he had removed on Thursday, in a case in which various diagnoses had been made and various modes of treatment had been resorted to, including electricity, but without benefit. The patient bade well to recover promptly.

Division of the Sterno-cleido-mastoideus for Complete Removal of the Cervical Glands.—DR. FRED. KAMMERER presented a man, and referred to two other patients, on whom he had extirpated all the glands of the neck to avoid recurrence in cases of large lymphomata; access to the glands being acquired by division of the sterno-cleido-mastoid muscle below. The wound was united by first suturing the muscle separately, then the skin separately, and the result has been normal mobility. He advised more common resort to this method of securing complete extirpation of the glands in tubercular enlargement and malignant disease, thus preventing reformation.

Humphrey's Operation for Anchylosis of the Jaw.—THE CHAIRMAN presented a young man, aged twenty-one, who when two years of age had scarlatina with suppurative otitis, which resulted in anchylosis of the jaw. He came to him when ten years old. The jaw seemed completely anchylosed on the left side. Possibly slight motion on the right. He then performed Humphrey's operation, cutting down on the left side, exposing the carotid artery and facial nerve, and removing the neck of the condyle. There was paralysis of the facial nerve for a short time, but the wound healed, and very good motion was obtained and had remained permanent. He also showed a young lady whose jaw had been anchylosed since the age of thirteen, when it sustained a fracture. The teeth and alveolar processes were in very bad condition, the jaw had rather an infantile appearance, yet the temporal and masseter muscles showed action, and he expected to get a good result from an operation. The ramus was shorter in her case, and a somewhat different operation would be performed, one similar to that done by Dr. Little in 1873. He remarked that bony anchylosis here was very rare; it was usually fibrous.

DR. GOODWILLIE referred to a case in which a surgeon had broken the muscle, when forcibly opening the mouth following an operation for anchylosis. Dr. Goodwillie was subsequently able to get a very good result by gradually opening the mouth by wedges. This method he thought would succeed where there was slight, though nearly imperceptible, movement.

DR. REGINALD SAYRE had also got very good motion in a nearly immovable jaw by wedging.

External and Internal Urethrotomy for Strictures following Gonorrhœa in a Boy Four Years of Age.—THE CHAIRMAN also read the notes of a case of gonorrhœa in a child aged three years and nine months, the disease having been contracted from a nurse. It was followed, six months after the discharge was supposed to be cured, by inability to pass the urine. He was taken to St. Luke's Hospital, where they were unable to pass the smallest instrument. The bladder was aspirated. There were three anterior strictures, and a tight one at the membranous portion which barely admitted a filiform instrument. The anterior strictures were divided by Otis's urethrotome, the posterior by external urethrotomy. The latter was found to be a tight, gristly stricture. Rather to their surprise, they found Dr. Bangs's suggestion correct, that the calibre of the urethra in this case, as was true in adults, was proportionate to the circumference, and after the operation a No. 24 French was introduced. The gonococcus had been present.

DR. BANGS said he had never before met with stricture following gonorrhœa in so young a subject.

DR. VAN ARSDALE, who had a dispensary class of female children, said he had seen many cases of gonorrhœa in the young. Within the past month three had come under his notice, the youngest being a female child aged only ten months. He saw about ten cases a year in very young subjects. The disease was very difficult to treat, because of the small size of the orifice. Eczematous eruption was likely to take place from the accumulated discharges, and to avoid this he passed a small sound made for the purpose. Being asked what he considered the origin, he said it was usually from sleeping with parents who had gonorrhœa.

DR. SYMES said he had formerly seen a good many cases of gonorrhœa in children, and on inquiry had learned that it often arose from a supposition, among the ignorant, that they could get rid of the disease themselves by giving it to somebody else.

THE CHAIRMAN said Dr. Willard Parker had given expression to the same opinion once, that the ignorant sup-

posed they would get rid of gonorrhœa by giving it to somebody else.

Dr. Agramonté thought the disease occurred more commonly among female children than among males, because of the accessibility of the genitals in the former to the filthy hands of nurses. But Dr. A. Van Arsdale thought the cases in the two sexes about equal in number.

The Mechanical Treatment after Vertebral Fracture.—Dr. John Woodbury read a paper and presented two patients with vertebral fracture, one operated upon by Dr. Charles McBurney, the other not operated upon. While confining his paper almost entirely to the after-treatment, he remarked that an operation had been resorted to in several reported cases, but it was to be observed that it was undertaken late, as a last resort. He suggested that an early operation, before serious changes had had time to take place in the cord, would probably offer much better results.

The case operated upon by Dr. McBurney was in a patient two and a half years of age, who in June, 1889, fell from a bed to the floor, striking upon the back. The history from June until August was comparatively a blank; whether paralysis came on immediately or later, it was impossible to learn; probably it was immediate. When admitted to the hospital, August 8th, the child was incompletely paraplegic; there was complete loss of sensation in the left lower extremity and also in the right, except in the great toe and sole of the foot. The child was very irritable, exceedingly emaciated; no temperature elevation. Dr. McBurney cut down upon the third, fourth, and fifth dorsal vertebræ, and removed thickening in the laminæ and in two spinous processes by rongeur forceps. There was no evidence of fracture of the body of any of the vertebræ; the dura was of normal appearance and was not opened. After the operation the irritability was much less, there was steady and rapid gain in weight, but the muscles of the lower extremities remained largely in their old condition.

The patient was turned over to Dr. Woodbury to give it support, which he found exceedingly difficult on account of the helpless condition of the body and limbs. Finally he resorted to a method of horizontal suspension and applied a plaster-of-Paris jacket. He made a hammock of four thicknesses of cheese-cloth, perhaps twenty feet in length, swung so that it could be put on any degree of tension. The child was laid on this, and slits cut, through which its arms and legs projected, and also one for the face. The legs held up by one assistant, the hands by another, any degree of extension could be made by pulling on the ends of the hammock. In this position the plaster-of-Paris jacket was applied over a knit shirt, the hammock also being included beneath it. The ends of this were cut off when the plaster hardened. Later the jacket was cut in front and made to lace like a corset. The child was now able to stand alone, and had regained control of the rectum and bladder. In the other case, in which no operation was performed, the child fell several stories down an air-shaft, and besides sustaining several superficial injuries, was unable to lift the head, the chin resting on the sternum. When lifted back it remained in that position. He was unable to say whether the first or second cervical vertebra or the occipital bone was broken. He placed the child in a plaster-of-Paris jacket, applied in the manner just described, and attached a jury-mast, after which rotation had been possible, and pain relieved.

Dr. Reginald Sayre thought great care had to be exercised in applying the plaster jacket in cases of fracture of the spine, if one was not to do more harm than good. His father had treated several cases of supposed fracture of the spine, applying extension and fixation by the jacket, the result in one having been a cure, in one paralysis remained, in a third the man looked strong and well, but became easily fatigued and was impotent. He could not imagine a better method of applying the jacket in these helpless, paralyzed cases than the one described by the author.

Dr. Samuel Lloyd referred to the case of an engineer who had been operated upon for an ununited fracture of the third lumbar vertebra, causing anæsthesia of nearly the whole right side below, of a small portion of the left side, and involving the bladder and rectum. These symptoms had progressively disappeared since removal of pressure by the operation, and the man was able to return to his work. He thought the cases narrated showed that we should look for gradual, not for immediate, improvement after operations for pressure on the cord.

Dr. Ketch was disposed to think the fracture in Dr. Woodbury's unoperated case was lower down than had been described.

Correspondence.

OUR BERLIN LETTER.

THE KOCH INOCULATIONS AND THEIR PROGRESS—OF NO USE IN ADVANCED CASES OF PHTHISIS—REACTION AS A PROOF OF DIAGNOSIS—SURGICAL OPERATIONS NECESSARY AFTER INOCULATION FOR TUBERCULOUS GLANDS.

(From a Special Correspondent.

Berlin, November 24, 1890.

As all the Berlin hospitals and most of the University clinics in Germany have now been supplied with and are using Professor Koch's specific lymph for tuberculosis, certain well-established facts which bear out Koch's claims for the remedy have been brought out by experience; but, as Professor von Bergmann said to day, there have been no patients cured yet.

Berlin has become the Mecca toward which many anxious faces and feet are turning, the sick to be healed and many hundred physicians to get the means to relieve those who are looking to the new remedy to help them, but both classes as yet are disappointed.

There are hundreds of cases under treatment here, and to the physician who has not seen the large number of cases of lupus under treatment, it does not seem possible to get fifty cases together in one city, but such is the case here, and more are coming in daily.

The first effects of the remedy are as well known now as they probably will be for some time, and the after-effects, especially the permanency of the so-called cures, will not be known for a number of months.

In phthisis pulmonum with large cavities the disease has not been arrested or cured, but has taken its usual course.

In the first stages there is the typical reaction—fever, chill, general malaise, etc.—the sputum loses its purulent character and becomes more glassy, while the bacilli gradually disappear, the night-sweats cease, and the appetite increases. But as Koch only claims that the tubercles are affected while the bacilli may remain, the question of getting rid of them will be an important one, and may require a return to our former remedies to promote calcification or healing of the affected parts.

It is in lupus that the specific action can best be studied; but even in these cases it is only the superficial and ulcerated tubercular nodules which are wholly destroyed; and though the deeper ones may be affected they are not cast out, and may, in other forms of the disease, remain a source of new infection.

A typical reaction is as follows:

First injection: In from four to ten hours temperature 40° C., accompanied by chill and vomiting. Second injection usually given in from forty-eight to seventy-two hours, when all symptoms from first have disappeared. Temperature 39° C., other symptoms not so severe, and fever does not last as long. Third injection: Temperature 38.4° C.; fourth, 38° C.; fifth, about the same as the fourth, and no reaction usually after the sixth or seventh, though it may be produced frequently by increasing the dose.

The local reaction is characteristic. There is congestion of the affected parts and scars, followed by a serous exudation which dries into crusts and this always takes place during the febrile reaction, though there may be reddening without fever. A number of patients have had an eruption which has the appearance of scarlet fever and is followed by a flaky (?) desquamation.

There are many variations from the type given, as the temperature sometimes goes up to 40.9 C., even after the third injection, and severe general depression, nervous symptoms, vomiting, and diarrhœa have occurred in a number of cases. In cases of diarrhœa it is possible that it is produced by the exudation from tuberculosis of the intestines. In hip-disease, white swelling, and tubercular bone disease the constitutional effects are the same, and the local are made manifest by increased soreness, reddening and the breaking of abscesses which are inflamed by the action of the remedy.

In cases where there are existing abscesses the constitutional and febrile reaction is retarded or slight, which might go to prove that the tubercles are already broken down. The surgeons who have used the remedy are agreed that it will be necessary to follow up the treatment by the usual surgical operations, opening of abscesses, resections, etc., to get rid of the broken-down tubercles and to prevent reinfection by the bacilli which may be present.

For the present it is thought that the greatest worth of the remedy is its value in diagnosis. We will know its curative value in the future when the first excitement is over and time has either verified or disproved present results.

HOW TO GET ALONG IN BERLIN.

(From a Special Correspondent.)

BERLIN, November 29, 1890.

WHETHER the student of medicine shall find Berlin a fruitful place for study depends on his advancement in knowledge. If he is in search of elementay instruction—the principles of obstetrics, the diagnostic methods of gynecology, or of general surgery—he can obtain excellent advantages. If he understands German—and it is nearly useless for him to come here without understanding and speaking it—the university courses now in progress afford all he could ask. For instance, in surgery daily clinical lectures are given by Professor Bergmann, and the students on his roll are called down into the amphitheatre, and required to describe, and, if possible, to diagnose some surgical case. Rather sad work they make of it at times, which is hardly surprising when we consider the circumstances. Great stress is laid upon description "What do you observe?" is the question put over and over by the examiner. If it be a tumor, then where, on what limb or surface, how shaped and bounded, movable or immovable, color, consistency resonance—all possible physical characteristics are sought and expressed in words. After this thorough observation comes the history, then the diagnosis is dwelt on at length, and all affections giving similar appearances are reviewed. The needful operation is then done by the teacher with consummate skill. No one who has seen von Bergmann operate, with strict precision and yet great speed, on case after case, can help feeling that he has been in the presence of a great master of surgery.

Bergmann's first assistant, Dr. Schlange, gives a fine course in practical surgery. The student is here called upon to make diagnoses, apply dressings, and even to perform operations.

In obstetrics and gynecology the student obtains at the Frauenklinik a good deal of practical work. He is drilled in the signs of pregnancy in the wards, does obstetric operations on the manikin, and is assigned confinement cases in the city. In diseases of women he is practically drilled in making examinations, and a few are from time to time invited to witness the operations. These are done usually about seven o'clock in the morning, an uncomfortable custom much in vogue in Germany.

And so with other branches—the skin, the throat, internal medicine. All these subjects are taught in a thorough and practical manner.

There come to Berlin, however, a goodly number of older men in search of special teaching. They have practised already perhaps ten years, and know pretty well just what they want. They do not care for didactic lectures, nor to be drilled on the signs of pregnancy, nor to do minor surgery under criticism. They come for advanced instruction—in the throat, or in surgery, or in nervous diseases—or perhaps they wish to witness laparotomies or the rarer obstetric operations. I believe I express the opinion of all the older men in Berlin when I say that for such instruction this city does not offer great or numerous advantages—certainly not during the semester. At this time the teachers give themselves up to the younger students. The difficulties which one encounters in the search for some sorts of post-graduate instruction are often exasperating. Suppose, for instance, it is gynecology which one wishes to work up. (I instance this branch because most Americans are interested in it.) First one looks to the University Catalogue, but it quickly appears that the lectures and clinics advertised here are for younger students. So of the courses advertised on the black-boards at the University, the Charité, the Frauenklinik, and other hospitals. It would seem natural that the University officers should give one information on such matters; but inquiry here elicits only a smile and a shrug. "How can I find what I want?" that is the question which agitates the minds of most of the older students who visit Berlin. It finally appears that one or two post-graduate courses are given in gynecology, but are never advertised—why, does not appear. Inquiry then elicits the discouraging information that one is already full, and the other perhaps will be given, or perhaps not.

But there is at certain seasons an effort made in Berlin to provide post-graduate teaching. In October, and I believe, in January, the privatdocents and other teachers offer what are termed *Ferien* courses in all branches of work. These last one month only, but, though much overcrowded, are interesting and profitable. At such seasons one has an opportunity of becoming familiar with many famous men's work. For example, one can learn Martin's methods in gynecology by attending his private hospital several times a week, and witnessing his operations. During this time one makes some examinations, and perhaps does some small operation such as curetting. But one learns most from observation.

Martin himself is a very stout man, and is assisted by an extremely fat nurse. She is nearly as remarkable a personality as the great privatdocent himself. She has invented several of his instruments, and his table for laparotomies. This is of galvanized metal and stands in a tub. It is only long enough to support the patient's head and trunk and hips. The lower limbs hang entirely over the end, and the operator sits between them. The room is very warm, and visitors lay aside coats and vests before entering. Everyone is expected to take a bath before attending these operations. The operator wears a rubber over-all and rubber boots, and when ready for work looks extremely like Captain Boynton about to take a swim. The patient is prepared in another room. While chloroform is being given, the mons, vulva, and abdomen are shaved and scrubbed, and the vagina is irrigated and cleaned with the hand. The patient is then

carried into the operating room, receives a final douching, and rubbing, particular care being bestowed upon the umbilicus. The abdomen is then rapidly opened by a generous incision, and the diseased organs examined and dealt with. Speed is considered of great importance. I have seen Dr. Martin operate for a small ovarian tumor and have the abdomen sutured in seven minutes, and again saw him remove a diseased ovary in six minutes.

During this time the stout nurse handles all instruments, threads needles, cuts ligatures, sponges out the cavity, and now and then wipes the perspiring countenance of the privatdocent. The only other assistant, except those giving chloroform and watching the pulse, sits on the patient's left, and holds the intestines out of the way. After the wound is closed the middle third of the table top drops, so as to permit the body-turns of a spica to be passed readily. All the cases observed passed through an entirely aseptic course, among them being ordinary ovariotomies and oöphorectomies, a vaginal extirpation of the uterus, and supravaginal hysterectomies—in one of which an enterorrhaphy had to be made, owing to a wound of the adherent intestine.

Other valuable vacation courses are held by eminent specialists in all departments. It is, however, difficult to avail one's self of as many as one would like, for the reason that the most desirable occur at about the same hour, and for the further reason that the hospitals and clinics are so widely scattered about the city that long rides in the street-cars are necessary.

OUR LONDON LETTER.

(From our Special Correspondent.)

URATOSIS—THE HARVEIAN LECTURES—SOME INTERESTING CLINICAL CASES—OPERATIONS FOR VESICULAR CALCULUS IN CHILDREN—THE RANK OF ARMY MEDICAL OFFICERS.

LONDON, November 12, 1890.

URATOSIS is the term proposed by Sir William Roberts to signify the deposition of the crystalline urates in the tissues or fluids of the body, considered as a separate pathological incident. He maintains that it would tend to clear conceptions of the subject if we were to isolate in our minds the precipitation of the crystalline urates as a detached and independent pathological occurrence, separate from all antecedent and collateral incidents, and erect it into a precisely definable symptom or physical sign apart from everything else. The presence of sugar in the urine was formerly regarded as synonymous with diabetes, but glycosuria was now regarded as a symptom, and we must add something thereto to complete our conception of classical diabetes. So with albuminuria and Bright's disease. Another example was the separation of venous thrombosis from phlebitis, with which it was formerly confounded. Sir William Roberts urged these views with some force at a meeting of the Medical Society, on Monday last. He suggested that we should, by adopting his proposal, gain several advantages besides that of avoiding a certain amount of circumlocution. We should, in the first place, bring into clearer relief the distinction between uric acid dissolved in the blood, and uric acid precipitated as crystalline urate—or, to use the new phraseology, the distinction between lithæmia and uratosis. The differences between these two conditions were important, and deserved more attention than they had hitherto received. In lithæmia the exact state of the uric acid was not precisely known. We were sure that it was not in the free state, because it was chemically impossible for uric acid to subsist in the blood-serum without entering into combination with the bases contained in it; but we did not know whether that combination was a quadrurate or a biurate, or a mixture of the two, or sometimes one and sometimes the other. On the other hand, in uratosis we knew exactly what we had to deal with; uratic deposits were composed solely of crystalline sodium biurate. It was an open question whether uric acid dissolved in the blood exercised any injurious effects at all, but we knew as a certainty that when uric acid was precipitated in the tissues as crystalline urate it did produce injurious effects. Lithæmia, again, was only an exaggeration of a normal condition; uratosis, even in the minutest degree, was pathological. He would suggest as possible that precipitation of the crystalline urates might occur, not only in the form of the coarse masses with which we were familiar in and about gouty joints, but also in the form of minute stars or detached crystals, which could only be detected with the microscope. It might turn out that the visceral neuroses, the thrombosis and embolism, and the occasional sudden death occurring in gout were not the result of any diffuse lithæmia, but were the consequences of microscopic uratosis in the substance of organs or in the blood itself. He hazarded this conjecture on the ground of some observations on blood-serum made by Sir Alfred Garrod and by himself. It would thus appear that in some cases of gout the blood might—though probably only very rarely—become so laden with uric acid as to be within striking distance of a general uratosis throughout the system.

Sir William Roberts also urged that the adoption of his proposal would enable us to discuss more freely, and with greater precision, the true relation of uratic deposits to the etiological factors concerned in their production. We spoke of "ordinary" gout and of "saturnine" gout. Would it not be a more accurate expression of the facts to speak of "gouty uratosis" and of "saturnine uratosis?" It was not easy to believe that lead-poisoning produced really and truly the same constitutional diathesis as that which existed in true gout. It seemed easier to believe that the gouty diathesis and lead-poisoning, while differing in all other respects, had one tendency or vice in common, viz., the tendency to uratosis. It was admitted that there were other factors which had considerable etiological force in the production of uratic deposits, and by adopting the nomenclature suggested we could conveniently indicate the concurrence of several factors in producing these deposits. We should also gain something in regard to a clearer apprehension of therapeutic indications. On the one hand, we could aim at minimizing the incidence of the predisposing cause—be that what it might—and, failing in that direction, we could aim directly at the uratosis itself. Uratosis was, like gravel, of and for itself a disastrous pathological accident, and it might induce consequences in the joints or in the kidneys of a permanent character, far exceeding in gravity and far outlasting the etiological factors which originally gave rise to it.

The "Harveian Lectures" for the present year are now in course of delivery; Dr. F. H. Champneys, Obstetric Physician to St. George's Hospital, being the lecturer. He commenced the course on Thursday evening last (November 20th), selecting as his subject that of "Painful Menstruation." He first discussed the changes occurring in normal menstruation. After considering the age of commencement and of cessation, the rhythm, duration, quantity, color, and qualities of the monthly flow, he briefly reviewed the causes of the non-coagulability of the fluid and the results of its microscopic examination. The changes in the uterus were then discussed, and the various views which had been propounded with regard to the monthly cycle. With respect to uterine contraction, there were arguments to be drawn from pregnancy, from fibroids, and from regurgitation ("menstrual hæmatocele"—"imperforate hymen"). The condition of the pelvic organs during the cycle could be learnt from fibroids, from the condition of the cervix and vagina, and by examining hernial ovaries. Menstruation was undoubtedly preceded by a sanguineous afflux to the pelvis, and was analogous to the onset of labor. Passing on, then, to the consideration of painful menstruation, Dr. Champneys remarked that pain must be within the "geni-

tal sphere," but the individual equation must be discounted. Discussing next the classification of dysmenorrhœa, the lecturer observed that there were really only two varieties, viz., inflammatory and spasmodic; of these, the inflammatory variety was not strictly dysmenorrhœa. The so-called "membranous" dysmenorrhœa was really a variety of the spasmodic form.

LONDON, November 29, 1890.

THE last meeting of the Medical Society was a clinical one, the evening being devoted to the exhibition of living patients. Among the cases shown were four of sporadic cretinism; the ages of the patients ranged from eighteen months to sixteen years, and in every one of the four cases the thyroid gland was absent. The cases were shown by Dr. M. Murray and Dr. W. Carr. Mr. Edmund Owen remarked that they were in reality examples of infantile myxœdema such as would theoretically result from removal of the thyroid. Mr. Owen showed two children in whom, when operating for cleft palate, he had snipped off the hamular process to relieve tension of the circumflexus palati muscle. Among other interesting cases exhibited was one of exophthalmic goitre in a woman aged twenty-four, who was shown by Dr. Sansom. When the eyes were opened, the exophthalmos was very well marked, but (owing to abnormal retraction of the upper eyelids) it disappeared when they were closed. Tremors, pigmentary patches, and most of the other signs of the disease were observable on this patient.

At the last meeting of the Medical and Chirurgical Society Mr. J. H. Morgan, surgeon to Charing Cross Hospital, read a paper on calculus of the bladder in children, in which he gave an account of 114 consecutive operations for stone performed at the Hospital for Sick Children, Great Ormond Street. In 75 cases lateral lithotomy was performed, with four deaths. Lithotrity was performed in 11 cases (3 of these were females), with 1 death. The supra-pubic operation was selected in 15 cases, with 2 deaths. Of the remainder, 9 were cases in which vesico-vaginal lithotomy was performed (no deaths), and in 4 patients a calculus was removed from the urethra. Mr. Morgan submitted the following propositions as the results of his experience: 1. That in children, small stones should be dealt with by lithoplaxy. 2. That oxalate of lime calculi, or stones of such size as not to be readily grasped by the lithotrite, should be removed by the lateral operation in the case of boys. 3. That in children the supra-pubic operation should be reserved for stones of very large size or inconvenient shape, or calculi embedded in a saccule of the bladder or impacted in the mouth of a ureter.

Dr. Marshall gave an account of twenty-seven lithotomies (26 lateral, 1 supra-pubic) which he had performed during the last twelve years; the average stay of a child in hospital after operation had been thirty-two days. His one supra-pubic case ended fatally. Mr. Morgan, he said, had made no reference to incontinence of urine as occurring after lateral lithotomy; it was observed in four or five of his own cases and continued up to puberty, at which period it ceased. He had himself been very unwilling to adopt lithoplaxy, but he now considered that most calculi in children should be treated by that method; he considered that very large and moderately hard stones should be removed by lateral lithotomy, and only very large stones (whatever their character) by the supra-pubic method. In employing lithoplaxy for children it was desirable to have several lithotrites and evacuators of different sizes, as it was sometimes advisable to complete an operation with an instrument of smaller size.

Mr. Buckston Browne said Mr. Morgan's statistics showed that vesical calculus was infrequent in children. He believed that lateral lithotomy would be superseded by the supra-pubic operation, as there was less risk of hemorrhage or of blood-poisoning, and the special risks of the lateral method were avoided; the supra-pubic method also gave the surgeon the advantage of being able to examine the bladder and stone with the finger.

Mr. Barwell said he did not agree with Mr. Morgan that the supra-pubic operation should be confined to the case of large stones. He thought that in girls the operation was preferable to the lateral one, which might leave a tendency to vesico-vaginal fistula. He believed a rectal bag was not necessary, as from experiments he had made and published he had shown that the fold of the peritoneum was not raised more than a quarter of an inch, and the base of the bladder was put into an awkward position for the operation.

Mr. J. Hutchinson, Jr., said he doubted whether the incontinence of urine, which might follow lateral lithotomy, ceased at puberty. He had lately seen a boy of eleven, who had been operated on at two and a half years of age, and in whom the incontinence was as bad as ever. In another boy, of fourteen, there were no signs of the incontinence ceasing.

Mr. Haward thought Mr. Morgan's results were favorable to the lateral operation. He had not himself come across the distressing results mentioned by Mr. Buckston Browne as following lateral lithotomy. He had seen a good deal of pain follow lithoplaxy, and did not consider distention of the bladder an entirely harmless proceeding. Though the supra-pubic operation might be easier to perform, yet, in face of the higher mortality, he would prefer to continue to practise the lateral operation.

The President (Mr. Timothy Holmes) remarked on the changes in procedure that occurred during the lifetime of a single man; he could remember the time when lateral lithotomy in children was considered the most successful operation in surgery. With reference to the accidents and sequelæ of the lateral operation, he could only recall one case of incurable rectal fistula. He was inclined to agree with Mr. Morgan's conclusions, if it was borne in mind that there was an enormous experience of lateral lithotomy in children in this country, whereas in lithoplaxy and the supra-pubic operation it was very small.

Mr. Morgan, in reply, said, that in seventeen years' surgical practice at a children's hospital, he could not recall a single case of incontinence of urine following lateral lithotomy. He thought that one reason why lithotrity had not been more extensively tried in children had been the difficulty of getting efficient instruments. That difficulty had now been overcome. He had not seen any cases of pain following the use of the lithotrite, and with the improved instruments he did not think it likely that any injury to the urethra would occur.

No speedy settlement seems probable of the question of "rank" as affecting army medical officers. The grievances of the latter are regarded by many as chiefly sentimental. The same term might be applied to many of the views on the subject, expressed by combatant officers. I believe that social pride is the chief root of the present difficulty. Many combatant officers, in short, look down upon the doctors, and some do not scruple to declare that the latter are their inferiors in birth, breeding, and education. The fact is that most medical men who enter the army do so to gain a livelihood; numbers of combatant officers do not, and the majority of them spend more than their pay. With many of the latter the army is simply regarded as a gentlemanly vocation—not as a career to be pursued with enthusiasm. The literary examination which officers have to pass is undeniably more severe than the entrance examination imposed on medical students, but of course the year's military training at Sandhurst cannot compare educationally with the four (soon to be five) years' course of medical study. I am not oblivious of the fact that many medical men are university graduates—some in arts, or science, as well as in medicine. At present, however, the conditions of army medical service are not such as to tempt many of these to compete for appointments. Army doctors, in fact, are not now the pick of the profession. The abolition of

regimental surgeoncies has done not a little to intensify the class feeling I have alluded to—a feeling which is of the same nature as that which has prevented a peerage ever being granted to a medical man.

ECTOPIC GESTATION.

To the Editor of the Medical Record.

Sir: In the discussion on ectopic gestation, before the Harlem Medical Association, reported in the last issue of the Record, I am made to say that "Electricity was not first used in 1872 for the relief of extra uterine pregnancy, but was first employed by myself for this condition in 1881." What I did in substance distinctly say, was that while the first case in which the method was attempted was as far back at 1872, yet its report carried with it no authority, and seemed to make no impression, and that it was not until 1878 that the subject excited any special attention among medical men. It was then that I treated my first case for Dr. McBurney, at the suggestion of Dr. Thomas, the publication of which by Dr. McBurney elicited no little comment, both favorable and unfavorable.

Other cases quickly followed, and the year 1878 rather than 1872 became, for all practical purposes, the real starting-point of this most beneficent therapeutic procedure.

Very truly,

A. D. Rockwell, M.D.

New York, November 22, 1890.

LETTER FROM SAN JOSÉ DE COSTA RICA.

A CENTRAL-AMERICAN REPUBLIC—SAN JOSÉ AND ITS HOSPITALS—LEPROSY IN COSTA RICA—PREVAILING DISEASES—A VARIETY OF CLIMATE—A LOW DEATH-RATE, AND A HEALTHFUL COUNTRY.

(From a Staff Correspondent of the Medical Record.)

Costa Rica, the southernmost of the Central American republics, is a little country of some twenty-one thousand square miles in area, having a population as near as can be estimated of about two hundred and twenty-five thousand. The people are for the most part white, and of Spanish descent, though on the Pacific coast there is a considerable admixture of Indian blood. There are comparatively few negroes except those who have been brought from Jamaica to work on the railroad leading from Port Limon to San José. These are all found on the Atlantic side of the country, so that the traveller, in crossing from ocean to ocean, passes through three strata of inhabitants, black, white, and red. The country is remarkably fertile, but only a limited area is under cultivation, as, owing to the small number of inhabitants, and the aversion to work which most of the people possess, there is a great scarcity of labor and it is therefore impossible at present to develop the country. While the cities of the north are crowded with people able and willing to work but who cannot find employment, this rich and healthful little country is unable to progress for the lack of inhabitants to work its soil.

The capital of the republic and its largest city is San José. It is situated almost in the centre of the country, in latitude 10° N., on a plateau at an elevation of 3,711 feet above the sea, and has a population of a little more than 25,000. It is at present very difficult of access, the only possible way to reach it from either coast being on mule-back over the worst roads that the mind of man can conceive. It is expected, however, that the railroad from Port Limon will be completed in a month or two, and then one can exchange the fatigues of mule-back riding for the perils and delays of the iron road.

Medical practice in Costa Rica is not very remunerative, the fee for an ordinary visit being fixed by law at one dollar in currency, equal to about seventy cents in gold. In San José there are some twenty-five doctors, and about the same number proportionately to the population in the other cities. In each of the provinces there is a hospital, that at San José being the largest. This hospital, called San Juan de Dios, was founded by a priest named Umaña, who left some houses and all his property for its maintenance. It is under the care of the Sisters of Charity, and contains one hundred beds. It is built in the form of a double quadrangle, one side being for men and the other for women, all the buildings being one story in height. At a little distance from this hospital is the leper asylum, where are lodged and cared for some ten or twelve lepers. There are known to be about twenty lepers in the country, those not in the asylum being isolated and under treatment in their own homes. These are all suffering from the anæsthetic form of the disease, and Dr. Calnek, who has medical charge of the asylum and has had some forty cases under his personal observation, states that he has never seen but one case of tubercular leprosy in the country, and that one was in the person of an Italian who had brought the disease with him from Europe. The subjects of the disease betray a rather peculiar mental condition. They have no hope of a cure, yet they are in no way depressed by the knowledge of their condition, but seem to be perfectly content, and welcome any addition to their company with smiles, apparently regarding the fact of his having become a leper as in the nature of a good joke. Dr Calnek has recently been using Gurjun balsam in the treatment of the disease with thus far rather encouraging results.

The most common diseases met with in the country are gastric affections, paludism in all its forms, and syphilis, the latter being almost universal among the soldiers and lower classes of the population, especially in and about the larger towns. The malarial fevers in the central plateau are comparatively mild, the pernicious forms being more frequent in the swampy regions on the coast. Diarrhœa and dysentery are very common toward the close of the dry season, being evidently caused by bad water, for they disappear almost by magic after two or three heavy rains. Some cases of pneumonia and acute rheumatism are met with, but they are not common, and the former is usually rather subacute in its course, differing markedly from the rapidly fatal disease so prevalent in the United States. There is more or less tubercular phthisis, but not so much as one would expect to find in consequence of the poor hygienic condition of the houses of the lower classes. These are all one story in height, and the floor, which is of dirt or brick, rests directly on the ground and is always damp during the rainy season. Typhoid fever and diphtheria occur from time to time in mild epidemics of slight extent and short duration. Yellow fever is found occasionally at the two seaports, Limon and Puntarenas, but is not endemic there. Several times cases have been brought from these ports to San José, and have died there, some in hospital, some in hotels, and others in private houses, yet the attendants, physicians or nurses, have never taken the disease, and in fact no case of yellow fever has ever been known to originate in the city.

The ordinary run of surgical practice is seen in the hospitals. Spinal and joint affections are rare, and all forms of tubercular bone disease are uncommon, although necrosis, due to traumatism, is rather frequent among the lower classes, where the custom of going barefooted is universal. A good many cases of fungus foot are seen among the peons, who never wear shoes. The disease is called fungus foot and looks like it, but it seems to be only the first stage of elephantiasis, a quite common affection in this country. Of affections of the skin all the ordinary forms are common enough, but scabies is said to have been unknown until about three years ago, when it was brought into the country by German and Hungarian laborers who were imported to work in the mines. Fleas inhabit the cooler parts of the country by millions, and scratching is a very necessary form of exercise in which all indulge.

The climate of the cities on the plateau is not particularly pleasant. The thermometer indicates a fairly even temperature, 55° to 75° F., but during the rainy season it is usually very damp, and at times uncomfortably chilly. During the dry season there is often considerable wind, which blows the dust in clouds through the streets. On the coasts it is much warmer, the mean annual temperature being from 72° to 82° F., but the heat is usually tempered by a fresh breeze, and the nights are always comfortably cool. The "cold lands" are found on the mountains at an altitude of 7,000 feet and over. Here the days are hot and the nights cold. Snow falls very rarely, but it is not uncommon to find the ground covered with hoar-frost in the early morning. Contrary to the usual belief, all these regions are comparatively healthy, and a foreigner need have no fear of disease anywhere in this country, even on the coast, except, of course, in the swamp lands, if he will observe a little caution. He should wear woollen underclothing, avoid getting wet (a rubber coat is an absolute necessity), and above all refrain from drinking the vile aguardiente of the country, which is to be found everywhere, and in which the natives indulge immoderately.

The death rate of the country was 25.64 per 1,000 in 1888, but of all the deaths 60 per cent. were of children under ten years of age, and if these are subtracted the mortality is reduced to a very low figure. During the year 1888 there were 367 deaths of persons over sixty years old, and of these there were 36 nonagenarians and 10 centenarians—not a bad showing for a country that is regarded as so unhealthy by the well informed (?) officers of life insurance companies of the United States that they demand an extra premium of one per cent. before granting permission to the insured to come here. If they knew a little more they would find it to their interest to offer a premium to all who would come to this health giving and health-promising climate, and thereby escape the dangers of a northern winter. They are conservative, perhaps, but their conservatism is born of ignorance.

San José, November 6, 1890.

A MODIFICATION OF SAYRE'S FRACTURED-CLAVICLE DRESSING.[1]

To the Editor of the Medical Record.

Sir: In a recent case of fractured clavicle where my patient, under the Sayre dressing, suffered great irritation from the adhesive plaster, he proposed substitutes for one part after another, until finally, between us, a new dressing was evolved. While dispensing with adhesive plaster, it meets the three classic indications by means both of the arm-leverage employed by Sayre, and of the scapula-leverage over the ribs as a fulcrum, so justly insisted upon by others as of cardinal importance.

The apparatus is simply this: A bandage, made wholly or in part of strong elastic webbing, starts with a loop around the middle of the upper arm of the injured side, passes backward across a thick compress over the lower angle of the scapula of that side, and divides to pass over and under the opposite shoulder, in front of which it reunites and passes across the breast to end in a loop around the elbow of the injured side. A handkerchief-sling around the neck for the forearm and hand completes the dressing.[2]

It will be seen that the one bandage draws the elbow forward and inward, while it throws the shoulder backward and outward, and brings the whole extremity upward. The elastic tension takes up the slack which is inevitable in a muslin bandage, and holds the parts in position more securely than even adhesive plaster, the best of which will slip in hot weather on a sweaty patient. It also exerts firmer pressure upon the pad over the lower angle of the scapula than is possible by an inelastic bandage, whether adhesive or not. This pressure, however, is made at the greatest disadvantage, the resistance being perpendicular to the line of traction. It is well, therefore, for the patient to sit in a high, square-backed chair (which may be improvised with a board), and rest the scapular pad against it; and to lie upon his back with a padded board under the affected side.

It occurs to me that the scapular-leverage could be most effectively brought into play by a stiff steel truss, with a well-cushioned pad on the scapula, a larger one on the sternum, and the spring passing preferably under the sound arm so as not to interfere with other appliances.

Respectfully yours,

John Winslow, M.D.

Ithaca, N. Y., December 1, 1890.

[1] Presented before the Tompkins County Medical Society, November 26, 1890.

[2] Should a transverse fracture or a cleido-acromial luxation require direct pressure upon the clavicle, this can be made by a pad on the point indicated and a second elastic bandage passing over it and under the elbow.

THE SURGEON'S DUTY IN EXTRA-UTERINE PREGNANCY.

To the Editor of the Medical Record.

Sir: The favorable termination of extra uterine pregnancy under modern surgical treatment is sometimes accomplished—we have on record quite a number of successful laparotomies resulting in the recovery of both mother and child. Now that modern surgery can at times save these cases and bring to the world a viable child, the question at hand is—what shall be the treatment of such cases?

A surgeon justly filled with professional pride at rescuing a mother by laparotomy from the dangers of an ectopic pregnancy writes that, "electrocution of living infants within the maternal envelopes must cease! an author writes of having killed thirteen infants by electricity! what a harrowing record"—I should like to know the probably harrowing result if the thirteen mothers had been treated on the expectant laparotomy plan?

He further states that his is the first maternally successful laparotomy after rupture of an ectopic sac recorded in New York, and the third in America, yet he advocates the expectant plan, boldly saying that "this imbuing of the physician's hands with blood of innocent infants must be frowned down and uncompromisingly condemned!" He says that a "woman must surrender her life for her infant," and that "with an ample incision and proper precautions, he sees nothing to fear." I beg to differ from him—I say a mother must not surrender her life for her intra abdominal child if it can be avoided, and I say that there is everything to fear in spite of "an ample incision and proper precautions."

Should this writer be unfortunate enough to meet another case of ruptured sac, the chances are that his opinions will be somewhat modified. Surgery to-day should *not* believe in the expectant laparotomy treatment of ectopic pregnancy. When statistics are more favorable to mother and child then will it be ample time to promulgate the very sanguine views of one flushed with the favorable issue of his first case.

The life of a mother is worth a hundred extra uterine fœtuses, and the rule at present is to save the mother by any way that will avoid the necessity for a laparotomy. Therefore I honor him who has "electrocuted" thirteen infants, and I say the record is not "harrowing" but pleasant to think over and digest at leisure.

We have here thirteen mothers saved and thirteen abdominal, fœtuses electrocuted. Grand record! Thirteen mothers saved without suffering, instead of two or three mothers and one or two motherless infants. I have no patience with the cold-blooded treatment that will allow many mothers to die, because a few infants may be born living from the abdominal cavity. A fœtus has no right to inevitably endanger its mother's life by wandering from its normal home, and if it does go astray it should

surely die, unless it remain undiscovered until viable, when it then may have a right to live if laparotomy is judged necessary. I consider the expectant laparotomy plan cruel and unscientific, when the ectopic pregnancy is diagnosed early. To order such a patient to be "placed on low diet, body kept at rest, and no active motions permitted," until laparotomy is indicated, probably months ahead, is barbarous treatment. From the stand-point of the theologian it has been decided that Cæsarean section should always be preferred to destruction of a living child, but Cæsarean section is not always done—the mother's right to live forbids it; should we leave the question of the treatment of extra-uterine pregnancy to the theologian, he would necessarily advocate the expectant plan; he believes it morally wrong to destroy even the germ of life, no matter where it may be. But we do not; physicians believe that mature life has a right to live, if necessary, at the expense of the beginning of life. The terrible and inevitable danger to maternal and fœtal life of an ectopic pregnancy compels physicians to save the mother's life in the easiest and surest way—hence "electrocution" is, and should be, tried in every case, and the expectant plan discountenanced, unless the patient and her friends, realizing the danger, desire to wait for a possibly living child brought forth by a necessary laparotomy.

R. ELLIS, M.D.

DANBURY, CONN.

CIRCUMSTANCES ALTER MALPRACTICE CASES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The wife of the gardener employed by a prominent citizen of a New York town is in rapidly failing health. The family physician calls in a consultant from a distance. It is agreed that the case is one of ruptured perineum, lacerated cervix uteri with metritis, and hemorrhoids, resulting from pressure, the uterus being immovably adherent low down in the pelvis.

The perineum is repaired, the hemorrhoids ligated, and the external mucous membrane of the cervix punctured in several places to relieve engorgement. It is not thought prudent to repair the lacerated cervix in such a weak woman at a time when the uterus is fixed among adhesions.

Hemorrhage from the cervix or from a slipped perineal ligature disturbs the family, but not the physicians. The perineum heals by primary union. The piles gradually return because uterine pressure continues. Glycerine tampons are applied to the uterus.

The patient remains weak and does not respond to treatment as she should, and the uterine symptoms assume a character that leads the surgeon to believe that the patient has a sarcoma of the fundus uteri. (Symptoms—steadily enlarging fundus; thin, reddish, serous discharge in abundance; marked pain and tenderness in entire pelvic region; paralysis of rectum; anorexia, and steadily failing health.) Intra uterine examination not feasible. Several months later it is discovered that the patient is pregnant, and that she was about four weeks pregnant at the time when the perineum was repaired. The former physicians are off on a summer vacation at the time when this discovery is made, and there being no one about who could correct false rumors, it is widely reported about town that the consulting surgeon had mistaken a child for a tumor, and that in trying to remove the tumor he had injured the patient and had left her a sufferer and an invalid.

Tea-parties and sociables are called in convention for a discussion of the matter. Certain colleagues who are not quite familiar with the case discuss it freely upon a basis of town reports, fearing that the latter may not be true, but hiding their fears.

The prominent citizen naturally sympathizes with his gardener's family, and believes that the surgeon is responsible for the patient's suffering. He is informed, however, that the patient's life is threatened because of pregnancy in the midst of complicated disease of the pelvic organs, and that the operation was beneficial as far as it could be in such a case. He is further informed that the operation was not performed after an erroneous diagnosis and that the later diagnosis of sarcoma was founded upon a sufficient basis. None of this information is believed by the citizen in question, and he advises his gardener to have the surgeon sued for "aggravated malpractice."

The patient does not act upon this advice, because she realizes that the sympathizing employer is misinformed. The husband of the patient tells the surgeon that several lawyers have been assiduously soliciting the case and trying to foment litigation, and that they have promised him money, stating that the surgeon would never allow the case to go into court. He also says that not members of his family but certain physicians should be consulted relative to false reports.

Several months later the gardener loses his position. He has a large family and is soon out of funds. Under the stress of circumstances he is misled and places the "malpractice case" in the hands of a reputable lawyer. His wife in the meantime has borne a living child and has retained the repaired perineum, but is very weak because of persistence of disease of the pelvic organs.

The lawyer writes to the surgeon stating that the case can be settled out of court for a certain sum of money, and that if this plan is not adopted the case will go before a jury. The surgeon in answer to the lettter simply tells the lawyer that he has been misinformed. The lawyer makes further investigation, and the matter is dropped.

ROBERT T. MORRIS, M.D.,

133 WEST THIRTY-FOURTH STREET, December 6, 1890.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 7 to December 13, 1890.

TAYLOR, MARCUS E., Captain and Assistant Surgeon. By direction of the Secretary of War, is relieved from further duty at Boise Barracks, Idaho, and will proceed, at the expiration of his present sick leave of absence, to Vancouver Barracks, Wash., and report in person to the commanding officer of that post for duty, reporting also, by letter, to the Commanding General, Department of the Columbia. S. O. 287, par. 17, A. G. O., Washington, D. C., December 9, 1890.

GANDY, CHARLES M., Captain and Assistant Surgeon, now on leave of absence. By direction of the Secretary of War, will report in person, without delay, to Colonel Eugene A. Carr, Sixth Cavalry, at Rapid City, S. D., for duty with troops in the field, reporting also, by letter, to the Commanding General, Department of Dakota. S. O. 287, par. 14, A. G. O., Washington, D. C., December 9, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 13, 1890.

BLOODGOOD, DELAVAN, Medical Director. Ordered to Charleston, S. C., to represent the Medical Corps of the United States Navy, at the meeting of the American Public Health Association.

AMES, H. E., Passed Assistant Surgeon. Ordered as delegate to Charleston, S. C.

BERTOLETTE, D. N., Surgeon. Detached from Naval Hospital, Philadelphia, and ordered to special duty in connection with World's Columbian Exposition.

DICKSON, S. H., Passed Assistant Surgeon. Detached from the Atlanta and granted two months' leave of absence.

WENTWORTH, A. R., Passed Assistant Surgeon. Ordered to the Atlanta.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 13, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	21	11
Scarlet fever	69	10
Cerebro-spinal meningitis	6	4
Measles	269	15
Diphtheria	120	31
Small-pox	0	0
Varicella	4	0
Pertussis	0	0

Hysteria in Childhood.—Much attention has been paid of late years, especially in France and Germany, to the psychical disorders of the young, and Dr. M. Duvoisin has made an interesting and valuable contribution to the subject in this paper. It deals with twenty-four cases which have occurred in the Children's Hospital at Basle within the last seventeen years. After references and criticisms of the most recent writers on the subject, the author expresses his agreement with Liebermeister in thinking that hysteria among children is the product of a functional disorder of the brain itself, particularly of the gray matter of the cortex. The cases arrange themselves into three groups: 1. The simplest forms (two cases, where the disease was characterized by alterations in character and general complainings). 2. Hysteria without convulsive attacks, and without loss of consciousness (11 cases). The symptoms of these were local pareses and paralyses, local hyperæsthesia or anæsthesia, aphonia, præcordial pain, etc. 3. Convulsive attacks, with or without pronounced loss of consciousness, such as Charcot calls chorea major, hystero epilepsy, and various atypical, casual, tonic and clonic spasms. In the etiology two great factors are prominent, viz., hereditary predisposition, present in more than half the cases, and a phthisical family history. All the patients but two were anæmic; debility, insufficient nourishment, etc., were also important factors. Twenty of the cases were girls, the remainder boys. The ages varied from seven years to fourteen. Full details are given of the symptoms and course of the cases while in hospital, and of their subsequent history to the present time. The disease is thus shown to have recurred in 14 cases after they left hospital. Diagnosis is often difficult, and the utmost care is necessary to avoid mistakes. The prognosis is found to be decidedly unfavorable, but dependent to a large extent on a continuous and careful management. The treatment, which, to be of any service, should be begun as early as possible, is to be directed toward two points: the cure of individual symptoms, principally by means of psychical influences, and the improvement of the general health. The former object may be attained, according to the nature of the case, either by entirely ignoring the disease, or by making the patient understand, in a friendly way, the serious results that may follow; or by energetically attacking and treating the symptoms by such methods as faradization, laryngoscopy, and the use of the œsophageal bougie. In the cases of chorea major, cold affusion, smelling salts, bromides, hydrotherapy, and amyl nitrite were found useful; but for permanent cure a long course of general tonic and nutritive treatment is imperative.—*Edinburgh Medical Journal.*

The Curve of Health.—Let me tell you one thing. I think if patients and physicians were in the habit of recognizing the fact that I am going to mention, both would be gainers. The law I refer to must be familiar to all observing physicians, and to all intelligent persons who have observed their own bodily and mental conditions. This is, the curve of health. It is a mistake to suppose that the normal state of health is represented by a straight horizontal line. Independently of the well-known causes which raise or depress the standard of vitality, there seems to be—I think I may venture to say there is—a rhythmic undulation in the flow of the vital force. The "dynamo" which furnishes the working powers of consciousness and action has its annual, its monthly, its diurnal waves, even its momentary ripples, in the current it furnishes. There are greater and lesser curves in the movement of every day's life—a series of ascending and of descending movements, a periodicity depending on the very nature of the force at work in the living organism. Thus we have our good seasons and our bad seasons, our good days and our bad days, life climbing and descending in long or short undulations, which I have called the curve of health. From this fact springs a great proportion of the errors of medical practice. On it are based the delusions of the various shadowy systems which impose themselves on the ignorant and half-learned public, as branches or "schools" of science. A remedy taken at the time of the ascent in the curve of health is found successful. The same remedy taken while the curve is in its downward movement proves a failure. So long as this biological law exists so long the charlatan will keep his hold on the ignorant public. So long as it exists the wisest practitioner will be liable to deceive himself about the effect of what he calls, and loves to think are, his remedies. Long continued and sagacious observation will, to some extent, undeceive him; but were it not for the happy illusion that his useless or even deleterious drugs were doing good service many a practitioner would give up his calling for one in which he could be more certain that he was really doing good to the subjects of his professional dealings.—Oliver Wendell Holmes, in the *Atlantic Monthly.*

Baltimore.—The new building of the College of Physicians and Surgeons is nearing completion and daily lectures are already given in the amphitheatre and lower lecture rooms.

The Ten-block System.—According to Mr. Bancroft's "Ten-block System," every road is divided into blocks of ten to the mile, each block therefore being 528 feet, or 176 yards, or 8 chains, in length of road frontage. Two house-numbers are assigned to each block, one on each side of the road. Every house in a block is given the number of that block; the first one having the number only, the others being distinguished by the letters of the alphabet in addition, as 96, 96a, 96b, 96c, etc. The numbers thus arranged indicate the distance of the house from the beginning of the road. As there are two numbers to each block, and ten blocks to the mile, to get the distance in miles the number of the house is divided by 2 and again by 10; thus, 96 divided by 2 gives 48, and this divided by 10 gives 4.8 miles, as the distance of the house No. 96 from the beginning of the road. The advantage of this arrangement to the country practitioner, and more especially to the city consultant called to the aid of the former, can hardly be overestimated.

Risks to Health in East Africa.—The colonizing wave setting steadily from Europe to East Africa gives peculiar interest to Dr. Kohlstock's experience of the risks to health and the chances of longevity among his compatriots in that region. As director of the sanitary arrangements at the German headquarters, he has had excellent opportunity of forming his opinions, and the sense of responsibility with which he gives them to the world is in some measure a guarantee of the care with which he has collected his facts and drawn his conclusions. The first note he strikes is one of warning. Let no one, in any stage of phthisis, even the pre-tubercular, think of settling in East Africa, if he does not want to leave his bones in its soil. At first this danger was not appreciated in the Fatherland, and the inspection of officers setting out with colonizing

parties was carried out in somewhat perfunctory fashion. But the climatic conditions of the region soon made their effects apparent, and nine subalterns had to be sent home —precisely those in whose families pulmonary phthisis had prevailed. For a man of thoroughly sound constitution the two diseases to be dreaded are dysentery and malaria. The former, in Dr. Kohlstock's experience, responds satisfactorily to the measures usually taken in European centres in the East—the disease among the German troops running generally as favorable a course as in French or English garrisons. The latter is dangerous only when the patient is precluded from taking rest and compelled to continue at work, as, for instance, on necessarily forced marches. Even so, but three fatal cases have as yet been recorded among the German troops in East Africa as due to malaria. As a rule, under conditions of rest the malaria patient soon gets well. In stubborn cases he has to be transferred to the sanatorium —the transference hitherto being effected on shipboard, in the absence of railways. Very often the change of locality, coming after the voyage, has sufficed to restore the patient's health. A liberal allowance of fresh butcher's meat has proved the most efficacious diet in malaria; indeed, the risks arising from the disease have been greatly reduced by the excellent nursing and accommodation now enjoyed by the patient. Dr. Kohlstock holds it to be a mistaken practice to completely cut off alcohol as a prophylactic against malaria; he would rather, within the limits of temperance, that the German in East Africa should live, as far as possible, as he did at home. The necessary upturning of the soil for purposes of tillage is, in such virgin territories as that of German Africa, the most prolific source of malaria, and, at that inevitable stage of colonizing operations, the sanatoria must be in constant requisition, and their treatment supplemented by change of locality for the convalescent. So well, however, have these measures been understood and carried out, that Dr. Kohlstock can point to a steady diminution in the statistical returns of malaria cases, the places where the disease has been most pronounced being, naturally enough, those like Mpwapwa, where the earth exhalations from the disturbance of long inert soil have been the most extensive, while no good water-supply has been obtained by boring. Next year, however, a marked reduction of the malaria returns will, it is hoped, be effected even in that locality.—*The Lancet.*

A New Local Anæsthetic.—Dr. J. B. Mattison, of Brooklyn, N. Y., writes: "The new local anæsthetic, first commended by Dobisch, of Zwittau, has served me so well that I think the MEDICAL RECORD readers may be glad to know of its value. Its make up is:

℞. Menthol ..... ℥ j.
Chloroform ..... ℥ ss.
Ether ..... ℥ xv.
M. Used as spray.

Though never pushed to complete anæsthesia—it is said to quite freeze the part in one minute—I have found it effective in superficial neuralgias, especially about the head, and if, in addition to its local use, a thin kerchief be placed over the face and the spray thrown on the nose and mouth, enough general effect—yet kept within safe limit—can be gotten to add not a little to the local good."

Prize Essay on Sanitation.—Dr. J. G. Orton, ex-President of the New York State Medical Association, has offered a prize of $100 for the best short popular essay on some subject connected with "Practical Sanitation," under the following conditions: 1. Competition to be open to all. 2. Essays to be forwarded to the Secretary of the Association, Dr. E. D. Ferguson, Troy, N. Y., not later than August 1, 1891, accompanied by the name of the author under separate seal. 3. Examination and award to be made by a committee appointed by the Council of the Association. 4. The successful essay to be read at the next annual meeting of the Association, and, if approved by the Council, to be offered for publication in the secular press, and issued in tract form, or otherwise, for general circulation. 5. Authors of essays, unsuccessful as far as the prize is concerned, but found worthy of special commendation, to receive intimation as to a proper disposition to be made of them.

Condition of the Heart after Death.—The old statement that in death from respiratory failure the right ventricle was filled with blood and the left empty, while in death from heart failure the left ventricle is filled, has recently been questioned, and Dr. Strassman has added a series of experiments to the literature of the subject. Dogs were killed with prussic acid, blows, stopping the trachea, strychnine, and hemorrhage. The heart was examined immediately after death, and in cases of primary heart failure (also when death was caused by a blow), the left side of the heart contained more blood than the right. In death from acute asphyxia the reverse was found. It is important that in no case, in any form of death, was the heart found in systole on immediate examination. The right and left ventricle were in diastole, soft and filled with blood, even in cases of strychnia poisoning. In the later examinations, twenty-four hours after death, the conditions were greatly changed. When rigor mortis sets in the left ventricle empties itself and strongly contracts, even in cases where death was caused by heart failure, and at first the ventricle was soft and overfilled. These phenomena are present in the right side of the heart to a less degree, owing to the weaker musculature. In those cases where rigor mortis is present and the ventricle soft and overfilled, the author thinks there is degeneration of the heart muscle. This condition was noted in two of the animals used for experiment: One was suffering from some infectious disease and the other died from prolonged chloroform narcosis. From the experiments of this writer we are justified in receding from the position of the older authorities that the condition of the heart as found post mortem is an index of its condition at the time of death. It is doubtful if the older observations of death from respiratory failure or heart failure are of any value, as the condition of the ventricle seems to depend upon the time that has elapsed since death.—*Journal of the American Medical Association.*

That there Is too much Minor Gyneecology at the present day is, says the *Boston Medical and Surgical Journal*, a very common opinion, especially among those who see much serious pelvic disease. A plea for greater conservatism was lately made by Dr. Joseph Price, before the Philadelphia County Medical Society, and was sympathetically received by the gentlemen taking part in the discussion. The overdone operations are the sewing up of the cervix, the dilatation of the cervix, the routine use of the sound, and the careless or routine use of electricity.

Everyday Hints for the General Practitioner.—A Tennessee doctor is credited with delivering two children with a pair of shoemaker's pincers, using the curved handles as obstetric forceps.

An Alabama doctor tells about a patient of his with neuralgia, who took a sharp-cornered rock and broke a hole through his cranium and poured swamp water in to cool off his brain.—*The Country Doctor.*

In a case of double compound fracture of the hips, Country Doctor writes us that, not having any apparatus handy, he had the patient placed in a plain coffin, which supported the bones well and gave good results.

In a case of severe hemorrhage from the stomach, in a patient fifteen miles from his office or any drug-store, the doctor, having no remedies at hand, did nothing. The patient immediately began to improve and ultimately made a good recovery.

A young man suffered violently from hiccough whenever he ate onions. Our correspondent asks for suggestions as to treatment.

A STUDY OF THE KOCH METHOD IN BERLIN.

BY H. P. LOOMIS, M.D.,

NEW YORK.

My trip to Berlin was undertaken with the purpose of obtaining a supply of Koch's fluid for Bellevue Hospital, and to study the methods employed and the clinical results obtained in the Berlin hospitals.

Through the courtesy of Professors Leyden, Gerhardt, and von Bergmann, I was able to study at leisure a large number of cases in their wards, to receive full instruction as to their methods, and, to some extent, obtain their impressions as to the effects of the remedy.

Upon arriving in Berlin, November 28th, I found that Professor Koch's discovery had become a matter of national importance. The medical profession, the people, the press, and the German Government had apparently forgotten, for the time, everything but Dr. Koch and the far-reaching importance of his discovery. The retiring bacteriologist was the lion of the hour.

The German Government, through its Minister of Instruction, Herr von Gossler, had publicly acknowledged Koch's claims to be verified, and a large sum of money had been appropriated for the erection of suitable buildings in which to test its efficacy upon tubercular patients. By these means Germany attested the truth and importance of the new discovery.

I shall endeavor to describe, somewhat in detail, the present status in Berlin of Professor Koch's discovery, and to give the result of my clinical studies of the cases observed. To simplify this, an arrangement under the following heads will be followed:

1. **The Fluid.**—How it is to be obtained; appearance; preparation for use; Koch's syringe.
2. **Method of Inoculation.**—Doses, etc.
3. **Results of Inoculation.**—Constitutional; local, in lupus and phthisis.
4. **Therapeutic Value** in lupus cases; in phthisis cases.
5. **Specific Action** on tubercle bacilli, sputum, night-sweats, general condition.
6. **Dangers of the Remedy.**
7. **Interesting Cases.**
8. **Conclusions.**

1. **Koch's Fluid** is received from Dr. Libbertz, after the payment of twenty six marks, the cost of manufacture. It is put up in glass-stoppered bottles containing about 8 c.c. The bottle is packed in a solid wooden box, which is sealed by a leaden seal stamped with the letter L. Accompanying the bottle are printed directions. On each box is a private number, enabling every bottle to be traced. The fluid is of a deep coffee-brown color, clear and transparent, has a burnt bouillon odor, and remains aseptic for an indefinite period. Dr. Libbertz, up to the present time, has received over six thousand applications for the fluid. Before leaving Berlin I was informed by Under-Secretary of State Aultolf that the German Government had not as yet taken the preparation of Koch's fluid into its own hands, as had been erroneously reported by the press; but that in behalf of the Government he was at that time carrying on negotiations with Professor Koch and Dr. Libbertz, which he hoped would place its manufacture into the Government's hands. This would relieve Koch, and guarantee a general distribution of the fluid and the integrity of its manufacture. Not until this is done will practitioners in this country be able to obtain it in sufficient quantities for general use. It is to be regretted that Koch sees fit to keep the composition a secret, for though there is no doubt that there would be great risk in its manufacture by those not skilled in bacteriological work, still, his present course greatly restricts its use. Probably one important reason which induced Professor Koch to maintain this reserve is, that he recognizes the power of the remedy and the dangers attending its use. It can be foreseen that a possible result of keeping the composition secret is that it might fall by dishonorable means into the hands of charlatans and be used by them for the purpose of gain

At the time of writing, the distribution of the fluid is solely in the hands of Dr. A. Libbertz, 28 Luenenburger Strasse, Berlin, undoubtedly under the direction of Koch himself. The difficulty of obtaining it is very great, owing to the limited supply and the extraordinary demand. As I understand it, the present intention is that Germany shall be first supplied, then the hospitals and asylums of Austria, America, England, and France, in the order named.

Those who are using the remedy most extensively in Berlin express the opinion that it is a solid medium, made liquid by unknown changes produced in it by the tubercle bacilli; that its efficacy is due to the presence of a powerful toxine or tox-albumin. Their opinion is only a matter of conjecture, for the secret of its manufacture is, as far as could be accurately ascertained, known only to Dr. Libbertz and Professor Koch's son-in law, Surgeon Pfuhl.

Preparing the Fluid.—For use the original fluid is diluted with a half per cent. solution of carbolic acid, which will preserve it aseptic as long as is necessary for continuous use.

One of the formulæ for preparation used in the Berlin hospitals is as follow:

℞. Original fluid..... ½ c.c.
Sol. carb. acid (one half per cent.)..... 50 c.c.

One cubic centimetre of the above will contain 0.01 c.c. of the original fluid. Sometimes they dilute the original fluid so as to make a ten per cent. solution, and then dilute this again to the required strength just before using.

Koch's Syringe.—The syringe which is used at the present time in all the hospitals and clinics in Berlin, with which to inject the fluid, is the one which has been known to bacteriologists for some years as Koch's syringe. The advantage claimed for it is that it can easily be rendered aseptic, for it has no piston, the action of a rubber bulb filling and emptying the chamber, which is of glass, and thus easily cleansed. This chamber is graduated to contain a c.c., which is subdivided into tenths. The syringe appears clumsy to one unaccustomed to its use, and to my mind has no advantages over an ordinary hypodermic syringe, especially when the latter is taken apart and thoroughly washed in an antiseptic solution before using. Since Koch has especially recommended his syringe as the one to use for injecting the fluid, it would be well to advise carrying out his directions to the letter.

2. **Method of Inoculating.**—The syringe is first filled with a ten per cent. solution of carbolic acid, then emptied and refilled with absolute alcohol; after being emptied of this, it is rendered perfectly aseptic and ready for use. Koch's fluid is drawn into the syringe to the graduation on the glass cylinder, indicating the strength of the original fluid to be used in a given case. Thus, one division on the glass cylinder would indicate that the fluid to be injected contained 0.001 c.c.; five divisions, 0.005 c.c., etc., In injecting, the needle is plunged into the skin of the back of the lumbar region and the bulb slowly compressed. There is no pain connected with the operation, nor any danger of an abscess, if antiseptic precautions have been taken.

3. **Results of Inoculations.** 1. *Constitutional.*—After a period varying from three to six hours subsequent to the injection, in the majority of cases, the period of reaction commences and the patients complain of severe headache, pains in the limbs or joints, chilly feelings, thirst, and dryness of the throat, sometimes accompanied by nausea and vomiting. If the case be one of pulmonary tuberculosis, cough and increased expectoration are almost constantly present, with occasional excessive dyspnœa. The temperature rapidly rises to 102° F., or even 105° F. All these symptoms gradually abate, the fever alone remaining high for from six to twelve hours, and the temperature then gradually returns to normal, which point it reaches generally within twenty-four hours after the injection. After the period of reaction has passed patients as a rule feel much improved, but sometimes the pains and malaise continue for a number of days. Irregularities in the reaction following the injections are often met with. In one case I saw it was delayed for forty eight hours; in another it was very severe and lasted for over twenty-four hours.

2. *Local.*—(1) In Lupus: About the time the reaction commences, as shown by the chilly feeling and the rise in temperature, the tissue, which is the seat of the lupoid changes, together with the surrounding healthy parts, has become intensely red, very much swollen, and feels, as an Englishman said whom I saw during the period of reaction, "as if a battle were going on in his face." A yellow, gummy, and thick, serous looking material exudes from the lupus surfaces, which becomes, in severe cases, of a dark brown color. By the time the fever has subsided the swelling of the lupus tissue has disappeared, and the ulcerations are more or less glazed over and a crust is formed. After several weeks this comes off and leaves a healthy-looking cicatrix, still marked from the surrounding skin by its red color. After the injection, small lupus nodules, which were invisible before, appear and stand out as granulations or white masses.

(2) In Pulmonary Tuberculosis: In the majority of cases large and small mucous râles appear over the affected area during the period of reaction. In one case I saw the physical signs of well-marked consolidation rapidly developed, where before the dulness was slight and the breathing rude. Pains in the chest over the affected area are a very constant accompaniment of the fever of reaction, often becoming quite severe. Also pressure, burning, irritation, unpleasant feelings (by no means always the same), are felt at the affected spot, showing that on this spot some specific action is taking place by means of the remedy. Upon listening to a chest a few hours after an injection, one can readily believe with Koch that changes simular to those one sees in lupus are going on in the lungs.

4. **The Therapeutic Value of the Remedy.** 1. *In Lupus.*—Standing by a case of lupus and watching not only the constitutional but especially the local changes which follow an injection, one is astonished to see an infinitesimal quantity of an unknown fluid produce in so short a time such plainly recognized effects, which are also limited to the diseased area. I saw seventeen cases of lupus, most of them patients in Professor von Bergmann's private hospital, all of whom agreed that they began to improve rapidly after the first injection. Their appearance confirmed the statement. In every case the lupus surfaces were cicatrizing. In some, cicatrization was almost complete, in others a number of injections were necessary to destroy the lupus. There was no case where benefit had not accrued and all promised a complete cure. One case, after being under treatment for eighteen days and receiving fifteen injections, returned to England, to all appearances cured. The case was of six years' standing and had resisted all known treatment, even six operations under ether had previously failed to stop the advance of the disease. Whether these cases are permanently cured and the lupus tissue all destroyed by the first series of injections, or whether subsequent treatment will be necessary to keep the disease in check, time only can show. Some lupus cases are made very ill by the injections, others suffer but slight constitutional disturbance. The difference seems to be a personal one, rather than to depend upon the amount of lupus tissue. One peculiarity of the injections was that lupus nodules were made apparent in places where they were before unsuspected, while in cases in which the lupus was apparently healed subsequent injections brought out local changes anew. In two cases I saw, as a result of the injections, an eruption, which resembled very closely a syphilide, appear over the entire body, but principally upon the chest.

2. *In Phthisis.*—It is in the treatment of phthisis that naturally the greatest interest centres, as lupus in this country is rare compared to its frequency in Germany It is folly to expect that in the short space of a few weeks a positive answer can be given to the inquiry, "What value has this remedy in the treatment and cure of phthisis?" Months must elapse before reliable data can be collected which will give the fluid its proper place and indicate the limits of its application, and, especially, prove whether the apparent cures are permanent. The ordinary strength of the injections used in phthisis in the Berlin hospitals is 0.002, 0.005, or 0.01 c.c., the proper dose to be used in each individual case being determined by trial. They usually begin with the smallest dose, one or two millimetres, repeated as soon as the temperature of the reactive period has returned to normal. The quantity injected is increased as the amount of reaction, as shown by the temperature range, diminishes. Rarely is the strength of the injection carried beyond 0.02 c.c. in phthisis, and by some clinicians it is kept below 0.005 c.c. On the other hand, much stronger injections are used in lupus, 0.02 or 0.03 c.c.

It appeared to me that the smallest injection of the fluid which will produce reaction is not only accompanied by less danger but produces better results, especially when continued over a long period. Professor Gerhardt had twenty-four cases of pulmonary phthisis in all stages under observation for two or three weeks. Eleven showed marked improvement, not only with regard to local changes but also in general condition, such as increase in weight, etc. He has almost abandoned the use of the remedy in cases of advanced stages. On the other hand, Professor Leyden, in a private conversation, said that he had seen marked improvement in some advanced cases of phthisis and would certainly advise the use of the fluid in incipient cases. These are the opinions of two men who have had the greatest clinical experience in the use of the remedy in phthisis. I am quite sure that I have seen harm done by the use of the fluid in pulmonary tuberculosis. I remember a case which was brought into the Charité Hospital in Berlin, with consolidation of one apex, and marked constitutional disturbance. Within a week, and after four injections, physical examination showed softening and the formation of a cavity in place of the moderate consolidation. The dyspnœa was intense, respirations reaching 60 per minute. The patient was made rapidly worse by the injections, and when I left, the case was hopeless. The result in this case I attribute to too frequent and too large injections. The manner in which cases of pulmonary tuberculosis are

treated by injections of Koch's fluid in most of the public hospitals of Berlin at the present time is subject to criticism. The hospital wards are crowded with patients in all stages of the disease. The cases are not thoroughly investigated before the injections are commenced, but as soon as they are admitted receive an injection, it may be of 0.005 or 0.01 c.c. These injections are continued daily, or every other day, until the patient has what is called a "good reaction," which may also mean a temperature of 104° F. No selection is made in the stage of the disease treated or in the condition of the patient. This is certainly not following Koch's instructions. The disastrous results, which occurred only in cases of advanced phthisis, followed. Where a large number of cases are treated, as in many of the wards of the Berlin public hospitals, these few unfortunate results should not be laid at Koch's door, but the unscientific treatment should bear the blame.

5. **Specific Action.** 1. *On the Tubercle Bacilli in the Sputum.*—In some cases after the first injection these were noticeably diminished, and after several injections, had entirely disappeared; in other cases no diminution in their number could be noticed. In one case I saw tubercle bacilli demonstrated in the sputum and yet no reaction could be obtained even by a 0.02 c.c. injection. In another case, of pleurisy, where there had been no cough or expectoration before injections were commenced, the patient commenced to expectorate after the second injection and tubercle bacilli appeared in the sputum. Thus it is seen that the action upon the tubercle bacilli in the sputum is not constant, even though they may be diminished in number. Professor Koch, in his original article, emphasizes the diagnostic value of his remedy. I believe, that, after the fluid has been used in a large number of cases, experience will show that, within certain limitations, this is not a fact. In external tuberculosis it will no doubt be of great diagnostic value, but not so in all cases of pulmonary tuberculosis. In Berlin the sputa of all hospital cases are examined daily, to note the effect of the remedy on the number of tubercle bacilli. The bacilli are counted in a number of slides, and recorded as "few," "abundant," or "moderate" in amount. While this method of obtaining facts is open to objections, still under the circumstances it is the best, and fairly reliable. In many cases the appearance of the bacilli in the sputum, under the microscope, is changed—they appear to be thinner and broken up, but this appearance is not solely characteristic of the condition following injections, for it has also been found under other circumstances.

2. *On the Amount of Sputum.*—In the study of cases under treatment in the hospitals a careful daily record is kept of the amount of sputum of each patient. After the first injection it is found to decidedly increase, but later to diminish; especially is this apparent after the third or fourth injection. The character of the expectoration also changes, becoming less purulent.

3. *On the Night-sweats.*—In almost all cases night sweats are stopped immediately after the first injection, and they do not return when the injections are discontinued.

4. *Improvement in the Patient's General Condition.*—The majority of patients seen in the hospitals said that they felt stronger and better, appetite had increased, and cough lessened. I place no reliance on these statements, however, for it is well known how liable phthisical patients are to see an improvement where any new remedy promising a cure is employed. Especially is this the case in Berlin, where the popular excitement over the new remedy is intense, and the patients are visited daily by large numbers of physicians. In only two cases did I see, after two weeks' treatment, any gain in weight, in one case two kilogrammes, in the other three. It must be remembered that the remedy had only been tried in the hospitals on an extensive scale for three weeks when the cases were examined, and Koch had explicitly stated that the increase in weight is only after four to six weeks.

6. **Dangers of the Remedy.**—Watching the effects of the smallest dose of Koch's fluid, one cannot but be deeply impressed with the dangers which must naturally attend its use, from the fact that it must contain a most powerful poison, to use which, indiscriminately, would be criminal. It should never be lost sight of that in direct proportion to the power of the remedy for doing good must be its capacity for harm. A number of deaths following the use of the remedy have been reported in Berlin One case which I know of was where phthisis was complicated by tubercular ulceration of the intestines. The remedy produced necrotic changes in one of these ulcers, which led to perforation and death. In a case of tubercular laryngitis, treated by injections, tracheotomy was required during the reactive stage to save the patient's life, the local swelling of the tissues of the throat threatened suffocation. The danger of the entrance into the blood current of tubercular tissue containing tubercle bacilli which has been rendered necrotic by the injections must also be thought of. A possible result might be an overwhelming of the organism by an extensive eruption of miliary tubercles in the different organs, so that it could not be controlled by subsequent injections. I saw cases in which so much of the lungs were involved that the large injections used produced reactions from which the patients never seemed to rally. They confessed to being made worse by the injections.

7. **Interesting Cases.**—To illustrate the action of the remedy and the range of its application, I will give the history of a few unusual cases now under treatment.

Case I. *Effusion in Pleural Cavity Produced by Injections of Fluid.*—Patient, a young man, aged twenty-six, six months before admission to the hospital had an attack of subacute pleurisy; recovered after four months, with adhesions and marked retraction of left side. On my first examination friction sounds were heard over the left side of the chest posteriorly. Patient at no time had cough or expectoration. After the first injection of 0.001 c.c., cough and expectoration both appeared, and tubercle bacilli were found in the sputum. Forty-eight hours after first injection a second was given of 0.002 c.c. After the reaction following this second injection had subsided I examined the chest and found the left pleural cavity half-filled with fluid. Professor Leyden afterward confirmed the diagnosis. The pleurisy in this case was, no doubt, tubercular in character, and the injections only made manifest a latent process. Marked reactions occurred in four other cases of pleurisy which I saw after injections had been given.

Case II. *Effects in Tubercular Meningitis.*—A child, aged eighteen months, suffering from tubercular meningitis, was inoculated with 0.00½ c.c. At the time of inoculation it presented symptoms of the stage of coma, was insensible to all impressions, pupils unaffected by light, etc. The child lived long enough to receive two injections, and though unable to save life at this last moment of disease, still produced most favorable changes. The general condition had improved, partial consciousness returned, and the pupils were becoming sensible to light when death supervened.

Case III. *Chronic Bronchitis and Emphysema Tuberculosis Diagnosed by the Injection.*—A woman, aged sixty-six, had been in the hospital for a long time suffering from what was diagnosed as chronic bronchitis with emphysema. Physical examination could detect no evidence of consolidation. Microscopical examination of the sputum showed no tubercle bacilli (fifteen cover-glass preparations were examined). An injection of 0.002 c.c. was followed by marked reaction. Physical examination gave evidences of well-marked consolidation below the angle of the left scapula. Tubercle bacilli appeared in the sputum.

I saw a number of what might be called "control experiments" made in the Charité Hospital. Non-tubercular cases were injected. Almost all the cases were free from reaction, even when an injection of 0.02 c.c. was given. I remember seeing two cases, however—one of scarlet

fever and the other erysipelas—which both gave reactions. We can well believe that they might have had a latent tuberculosis, hitherto unappreciated. A very few cases which were undoubtedly tubercular did not react at all, or only slightly. Two of these were cases of pulmonary tuberculosis with amyloid changes. Possibly time may show that there are certain special tubercular processes which do not react.

8. Conclusions.—If I were asked to express an opinion as to the efficacy of the new remedy, I should say I believe it to be as great a medical discovery as that made by Jenner; that it opens up a hitherto unknown field in the treatment of disease, which no one at the present time can limit; that it apparently cures lupus, as admitted by all observers. With regard to its curative power in pulmonary tuberculosis, I would like to quote the answers made to a series of questions, which Professor Leyden permitted me to ask him a few days before leaving Berlin. There is no one whose opinion as a clinician could be more valuable.

1. Have you noticed any *permanent* improvement in cases of early phthisis following the use of the remedy? Yes, but time can alone show how frequent such cases are.

2. Have you seen improvement in advanced cases? Yes, in some.

3. Would you use the remedy on your own child? Yes.

4. Do you favor its use in private practice? Yes.

5 Have you seen any disastrous effects following its use? Yes, in unsuitable cases and in overdoses.

6. What precautions should be taken? Employ small doses until personal effects are noted. Begin with 1 to 2 or 5 milligr.

7. Do you continue constitutional treatment while using the remedy? By all means. We have to do with a most extraordinary remedy, whose specific action is on *local* processes not constitutional.

8. Would you give the remedy to a child? Yes, in half milligrammes.

9. What is its diagnostic value? It has no *positive* diagnostic value in all cases.

DOUBLE INGUINAL HERNIA IN A HERMAPHRODITE.[1]

By CHARLES N. DIXON JONES, M.D.,
BROOKLYN, N. Y.

GENTLEMEN: I have in this jar two specimens of hernial tumors which were removed, by operation, from the inguinal canal of a hermaphrodite. The patient, Emma M——, twenty-one years of age, has been reared to the present time as belonging to the female sex, but investigation proves that the patient is a true representative of transverse hermaphroditism, although of an unusual type.

This patient consulted me on December 2, 1888, for a double inguinal hernia and amenorrhœa. The hernia was on both sides and of the ordinary type of inguinal hernia. At times it was very painful, so much so that she could not attend to her work. The patient had never menstruated nor had any symptoms of menstruation, nor was there any history of a vicarious menstruation. The patient's mother had eight daughters, two of whom were affected in a similar manner. Dr. S. G. Webber, of Jamaica Plains, Mass., wrote me that one of them had never had her catamenia and had congenital absence of the uterus.

This patient was large in stature, and has the appearance of a handsome, well-formed woman; thorax, pelvis, and body generally were of the feminine type; mammæ and nipples were fairly well developed; the voice is feminine, though the larynx is more protuberant than is usually found in the female. The external sexual organs were those of a female, and in general well formed, the clitoris and nymphæ were perhaps smaller than natural, and the orificium was rather contracted, and partly shut by a hymen. The fossa navicularis was distinct and the vagina normally situated, but extremely short and narrow, not more than two inches in length, and at this upper extremity terminating in a blind cul-de-sac, without any trace of the uterus or of the tubes or ovaries.

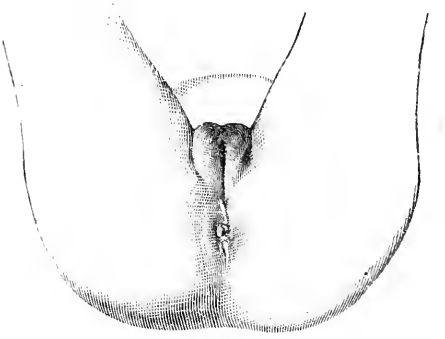

FIG. 1.

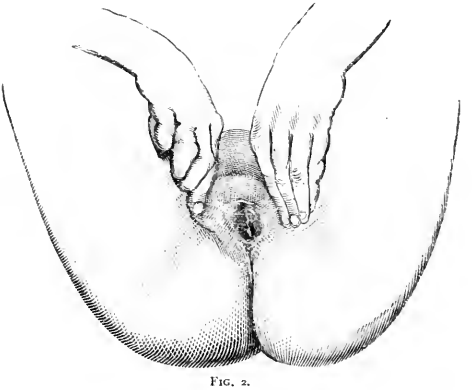

FIG. 2.

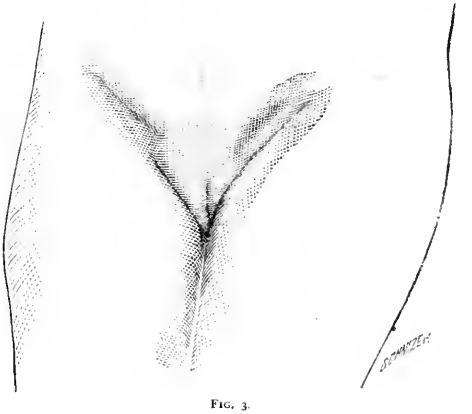

FIG. 3.

[1] Paper presented before the Medical Society of the State of New York, February, 1889; subsequently read before the Brooklyn Medical Microscopical Society, with demonstrations of microscopical structure and presentation of micro-photographs made by Dr. C. N. Hoagland.

Even under ether and by combined vaginal and abdominal examination there could not be detected the least tumor, or swelling, or anything resembling the uterus, or ovary, or the Fallopian tubes; but in the region of each external abdominal ring there was a hard body which I then judged to be a prolapsed ovary. These bodies were extremely sensitive on pressure, and they were irreducible. The pain in these enlargements was becoming more distressing and more intolerant; the patient was very desirous of having them removed or being relieved of the herniæ, and evidently it was best for her welfare and comfort, so an operation was advised. Preparations were made as for a laparotomy. Upon cutting down on the hernial bodies I came upon a firm fibrous envelope enclosing the organs in a sac; upon opening this I could find no communication with the peritoneal cavity, except by some firm, fibrous bands which attached the organs to the internal surface of the abdominal wall. Before tying and severing the pedicles, and in order to be certain that no abdominal organ was included in the neck of the sac, I made a medium abdominal section and examined the site of the tumor from within. I could only feel a fibrous cord running downward and backward from the internal aspect of the internal abdominal ring and becoming lost in the floor of the pelvis. From this internal examination there was still found no trace of the uterus or other sexual organs.

I then closed the abdominal wound, tied the pedicles with a strong silk ligature, removed the tumors from each side, and then closed and dressed the wound antiseptically. The patient made an easy recovery and says that she has been in better health, and more comfortable ever since.

I present herewith the organs removed, together with the photographs of the same and of the patient, before and after the operation.

Plate 1 represents the external genitals.

Plate 2 represents the parts more minutely. The labia are separated so as to show the clitoris, the opening of the urethra, and the entrance to the vagina.

Plate 3 represents the scars left after the operation. Female type of the pelvis.

Plate 4 represents the right testicle removed.

Plate 5 represents the left testicle removed.

As is well known, the ovary sometimes passes through the inguinal canal and forms a hernia; these cases are usually congenital. The only similar case to the one

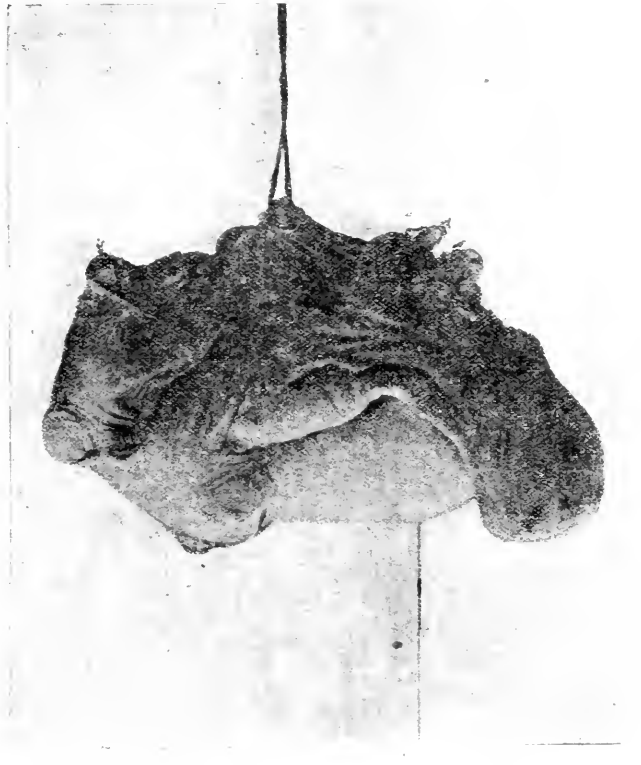

Fig. 4.

above described that I have been able to find recorded is reported by Koltz.

"An individual, aged twenty-four, with rudimentary penis, had two lateral elevations on the genitalia; the right one began to grow at the age of sixteen, and attained twice the size of man's fist.

"Violent pains in the tumors were felt every month and after the eighteenth year were accompanied with a discharge of blood from a fistulous opening. Billroth extirpated on the left side a normal testicle, and on the right side a cystoid tumor, with gland-like structures, which were lined with epithelium and had colloid contents, but did not form well-developed follicles. A fallopian tube, round ligament, and right-sided uterus and unicornis were present."

The specimens which were removed from Emma M—— have been examined by Dr. C. Heitzman and pronounced to be testicles.

I am inclined to believe that many of the cases which have been reported to be ovarioocle on closer investigation might have been found to be undescended testicles in hermaphrodites.

Leopold has described a case where the individual, at the age of twenty-five, was married as a female. She had never menstruated. There existed only a cul de-sac instead of a vagina, the clitoris was small, and in general the appearance of the external genitals simulated the female. In the labia were two round, almond shaped bodies. There is no post-mortem history.

Cases in which the ovary has passed through a hernial

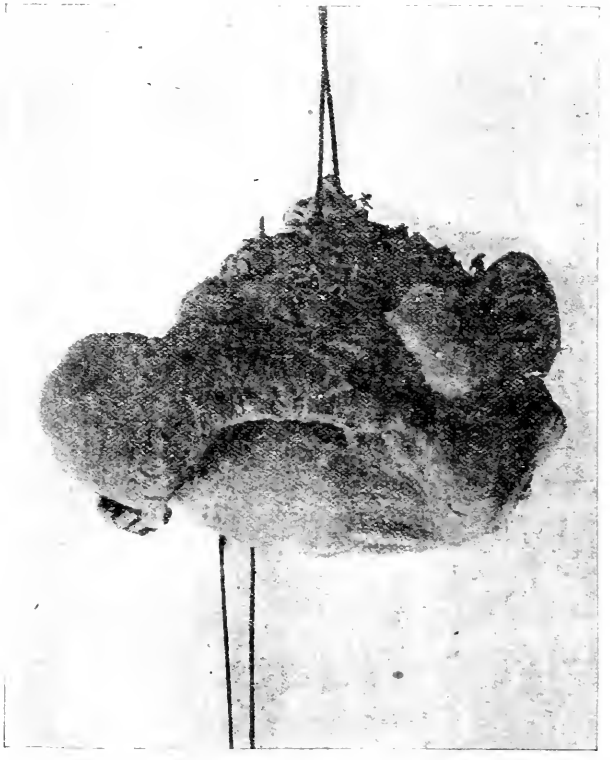

FIG. 5

opening are not infrequent. Absence of the uterus has been frequently noticed. Such cases are described by Maschka, Leopold, Werth, Koltz. It is not at all unlikely that if an operation had been performed and microscopical examination made, some of these organs would have proved to be testicles, or cases of cryptorchidismus in hermaphrodites.

The Manufacture of Spermine from the testicle is a complicated process. Schering's chemical works have taken in hand its synthetical production, according to a process described by Professor Ladenberg. The basis (which is probably identical with spermine) is C_2H_4NH—ethyleneimine. It is a crystalline substance, small needle-shaped crystals, is easily soluble in water, and tastes slightly of ammonia. It will dissolve a large amount of urea.

REMARKS ON THE INTRAPULMONARY AND SUBCUTANEOUS TREATMENT OF TUBERCULOSIS.[1]

BY JOHN BLAKE WHITE, M.D.,

PHYSICIAN TO CHARITY HOSPITAL, NEW YORK, ETC.

IN the MEDICAL RECORD of November, 1886, I had the pleasure to report the progress of a patient, suffering from pulmonary tuberculosis, under intrapulmonary treatment, as first practised by Dr. Pepper, of Philadelphia, and subsequently by Dr. Beverley Robinson, of New York, and myself.

The method of treatment was the same; but I used a formula which I found to be absolutely free from any irritating effects when injected into the lung cavity, and in every instance marked benefit was observed in all the distressing symptoms of this dread malady. The cough and expectoration were always lessened, the temperature invariably lowered, and night-sweats checked for several successive nights, and a marked general improvement was the rule for several days after each intrapulmonary injection. The case which is referred to above is a living evidence to-day of the value of this method of treatment. While this patient was receiving the intrapulmonary injections she was under the observation of Dr. Ira B. Read, her physician, and was seen by Dr. J. Lee Morrill, Dr. W. T. Alexander, and my father, Dr. O. A. White. The sputum was not examined at the time for bacilli, as the case appeared so characteristically one of advanced phthisis that we all thought it quite unnecessary. However, a few months after the patient was discharged, with a healed cavity and restored health, she was exposed to inclement weather and contracted a severe cold, which established a consecutive catarrhal condition at the previous seat of disease. I had the sputum examined at this juncture by my friend Dr. James R. MacGregor, who has paid considerable attention to bacteriological research, and he reported the presence of tubercle bacilli in the sputa furnished him.

At this time the patient received two intrapulmonary injections at the interval of a week, and these arrested the pulmonary affection promptly, removing all cough, expectoration, etc.

Subsequently I was consulted by Dr. P——, of Malone, N. Y., who desired me to carry out my intrapulmonary treatment in his own case. He was found to have a large cavity at the apex of his right lung, and to be troubled with a large amount of expectoration, incessant cough, night-sweats, loss of appetite, and much general debility. He being over sixty-two years of age, I hesitated to undertake the treatment, and yielded only to his persistent request. I directed him to a neighboring hotel, where I injected the cavity with the pulmonary fluid which I had been in the habit of using, and the result was eminently satisfactory. My friend Dr. J. Lee Morrill very kindly offered me his aid in the operation, having previously verified the diagnosis. The operation was followed by no unpleasant reaction, and the next day the patient visited some friends out of the city.

The second day after the operation he walked to my office from the Long Island Ferry, East Thirty-fourth Street, a distance of two miles, declaring that he felt no

[1] Read before the Northwestern Medical and Surgical Society, December 17, 1890.

ill effects whatever from the exertion, and had not experienced any since the operation; but, on the contrary, felt stronger, and thought his respiration improved. He assured me that his cough and expectoration were lessened, and he had no night-sweats since the operation.

Dr. P—— went to Southern California, where he received the same treatment, carried out by Dr. Northrop; but when he wrote me that each operation was followed by hæmoptysis, I advised a discontinuance of the treatment. He felt, however, that the injections had benefited him, and three years after our first interview I was surprised one morning to see the doctor walk into my office, so much improved in his physical condition that at first I failed to recognize him. He had gained in flesh, appeared strong for a man of his years, and was very enthusiastic over his experience with intrapulmonary injections. Upon examining the right lung I found the cavity had thoroughly cicatrized and contracted, so that no further treatment was deemed necessary. Dr. P—— was, however, quite ready and anxious to have the intrapulmonary injections continued if thought advisable.

In view of the results obtained in these cases, together with other favorable experiences with the intrapulmonary injections, I have been, these past years, induced to continue them in all cases demanding this treatment. I have been so gratified with the intrapulmonary use of my composition that I have latterly adopted the subcutaneous insertion of the same fluid, graduated in quantity, to suit each patient's age and susceptibility to the hypodermic medication. Improvement invariably follows these injections; the cough, expectoration, and night-sweats are controlled, and the patient describes a pleasant glow pervading the system, while a sense of greater strength continues for a day or more.

I usually begin with ten minims, gradually increasing the dose to sixty every day.

The formula was published in the MEDICAL RECORD, May 22, 1886; but it is now prepared with some slight modification, as care is necessary to avoid a precipitation of the alkaloids—the only difference being in the substitution of distilled water for diluted alcohol. The fluid is a clear, reddish-brown liquid, of a not unpleasant odor, and is entirely non-irritating either under the skin or when injected into pulmonary cavities. For this method of treatment I have in some instances substituted the subcutaneous injection of the chloride of gold and sodium and iodide of manganese, guarded with a small amount of morphia or codeia and atropia—these last being added for their well-known effect in allaying irritation and controlling the night sweats. The cyanide or the iodide of gold is especially indicated in cases with laryngeal complication, relieving spasm of the larynx and allaying irritable cough largely occasioned by the throat ulceration. The results from the hypodermic use of these remedial agents have been such as to warrant further careful tests of their merit. It is not my intention or desire to excite undue expectations from these remedies, but simply to detail the results of experience, and to request my colleagues to look into their claims for recognition as potent agents in the debilitating conditions associated with phthisis, scrofula, sy[illegible]

posed at this time by Kaposi, who, during a twenty years' experience, had seen one thousand two hundred cases of lupus, and had never noticed any connection between it and tuberculosis. Many of those at the present day who believe that lupus and tuberculosis are not identical diseases, still admit that there must exist an intimate relationship. If the bacilli found in the two processes are not the same, they must be at least first-cousins, and the experimental treatment now in progress, if it does not prove positively and permanently curative, may at least serve to clear up these disputed points.

Reported cures of lupus have already been made, but keeping in mind the well-known tendency of the disease

the notice of the profession the different preparations of gold, and they have since been used with advantage in secondary syphilis and syphilitic ulcerations, "especially those of a leprous character."

The chloride of gold is the most virulent of the preparations, even more active, according to Christien, than corrosive sublimate. When taken in overdoses there results severe pain, inflammation, and even ulceration of the stomach and bowels, acting in every way as a corrosive poison. In moderate doses the general effects of these preparations is to occasion increased fulness and excitation of the pulse, an increase in the quantity of the urine and perspiration, without in any degree interfering with the appetite or regular action of the bowels. When the dose is pushed too far a general irritation follows, *inflammation seizes on some organ, in accordance with individual predisposition, and fever is developed.* It will be noted that the remedy has a special direction to *the existing morbid process;* the effects being more marked in the external tubercular lesions, and is a most important characteristic of the gold preparations.

M. Chavannes has used the remedy to advantage as a caustic in lupus and in syphilitic tubercles and ulcers.

M. Pourché has observed very satisfactory results fol low the use of cyanide of gold in syphilis and scrofula, and considered it less exciting than the double chloride when used similarly.

As these preparations are liable to undergo decomposition when kept; they should be excluded from the light and prepared only for immediate use.

The trials which have been made with the combinations of Manganese place this metal on a par with iron as a tonic and anti-anæmic. It is present always, in small proportion, in human blood, as well as in the other fluids and solids of the body. In the anæmia associated with phthisis, therefore, it is especially a useful addition to its therapeusis, and is far more readily assimilated when subcutaneously administered than when taken into the stomach. A special usefulness is claimed for the iodide of Manganese by M. Hannon in the anæmia associated with scrofula, phthisis, cancer, and the syphilitic cachexy. M. Hannon tried the carbonate of manganese on himself, and, after its use for fifteen days, found his appetite improved, his pulse increased in force, and experienced a feeling of "sanguineous plethora." He subsequently gave the remedy in several cases of anæmia, and found that it excited the functions to a more healthy action; increasing the strength and improving the quality of the blood.

A knowledge of these experiences led me to believe that these agents possessed, in combination, valuable therapeutic effects when used subcutaneously, and I therefore began a few experiments, which were followed by such marked benefit in phthisis that I feel justified in offering my experience to the profession, with an assurance that in many instances they will not disappoint those who carefully and skilfully use them in the manner suggested.

In incipient phthisis the metals will act more actively than in the later stages of the disease; but even in these cases benefit will result, and, if combined with the intrapulmonary injections, some cases may be found very decidedly improved by the two methods of treatment.

In phthisis laryngea the spasms dependent upon the local lesion will be much relieved by the subcutaneous injections of the gold preparations with the iodide of manganese.

I have found physical improvement follow the continued use of these agents as described.

The patients now under treatment have shown a decided tendency to improve. One case of laryngeal phthisis has manifested great amelioration of the symptoms due to the laryngeal lesion, in addition to a general favorable reaction, since the injections were begun. The appetite I have found to be increased, the fever is lessened though at first increased, and the expectoration also modified in quantity and quality, the cough and night-sweats are markedly controlled, while other evidences of benefit have

been observed. The quality of the expectoration is changed from a muco purulent to a more frothy mucous character.

I have not seen, in all my experience with such cases, a method or a course of treatment with any remedy yield such promising results as I have realized with these remedies administered under the skin.

Great caution is to be exercised in the use of these preparations, as they are powerful poisons and require more than ordinary judgment in estimating each individual susceptibility.

At some future day I hope to detail more in full a report of my clinical experiences.

1013 Madison Avenue.

Progress of Medical Science.

Bradycardia, or Slow Action of the Heart.—The cases hitherto recorded of "slow heart" and the inferences derived from them are not altogether satisfactory, as many errors have arisen owing to the pulse having been only taken at the wrist and not compared with the apex beat. Dr. Riegel has made observations on 1,047 patients whose hearts beat less than sixty times per minute. Such a condition he terms bradycardia. He divides his cases into two large groups: 1. Physiological bradycardia. By this Riegel understands a slowing of the heart's action, caused by, or in connection with, some physiological condition. Under this head would come the "slow heart" occurring in puerperal states, also that which is found in cases of starvation, and finally, the bradycardia which is sometimes observed as a constitutional peculiarity. Riegel here remarks that many of the cases of this kind which have been reported are greatly open to question, as some of them were obviously due to some pathological cause. 2. Pathological bradycardia. There are several varieties under this head: *a*, The slowing of the pulse noticed in convalescence from a febrile affection. More than a quarter of the whole number of cases were of this kind. They were most commonly observed after recovery from croupous pneumonia; then, in order of frequency, after typhoid, erysipelas, and acute rheumatism. Traube attributed this phenomenon to a state of general exhaustion. *b*, Bradycardia in diseases of the digestive tract. In this division were 379 cases. It was most frequently noticed in affections of the stomach (ulcer, carcinoma, and dilatation). Such a result might have been inferred from physiological experiments; for in animals an increase of arterial tension with diminution in frequency of the pulse takes place when the stomach is submitted to electric, mechanical, or thermic excitation, and is caused by a reflex action of the vagus. The slow pulse of icterus probably depends on the paralyzing action on the cardiac ganglia by the bile acids in the blood. When occurring in cases of peritonitis, the bradycardia is probably of the nature of those cases described in the first division. 3. Bradycardia in diseases of the respiratory organs. In this class were 87 cases. Some of them were during convalescence from pleurisy; others after hæmoptysis, or after the withdrawal of a large pleural exudation. 4. Bradycardia in cases of disorders of the circulatory organs (47 cases). This phenomenon appeared in fatty degeneration of the heart and when the coronary arteries were ossified, but it was never found as a constant symptom of any one disease of the heart; it more often occurred when the heart was flabby and insufficiently nourished. 5. Slow heart in diseases of the urinary organs (64 cases). Acute nephritis was the most common disease in which it was found; the slowing of the pulse was always accompanied by increase of arterial tension, and was often the earliest sign of the retention in the blood of the urinary constituents, thus denoting the commencement of uræmia. 6. Bradycardia as a result of poisoning. Riegel noticed it in 3 cases of lead poisoning and in 5 cases of chronic alcoholism. 7. A pulse under 60 per minute was noticed in 27 cases of anæmia and chlorosis, in one case of extreme anæmia after lead-poisoning, and in 3 cases of diabetes. 8. Bradycardia in diseases of the nervous system (93 cases). In many of these cases it was thought to be due to reflex vagus action. In some instances of disease of the central nervous system it was probably caused by direct vagus action; in others Riegel ascribed the symptom to disturbances of the circulation and blood pressure in the brain; and in the remaining number of cases no definite action could be distinguished. 9. Bradycardia in other diseases. Under this head were 17 cases of extreme fatigue and exhaustion, 1 case of sunstroke, 12 cases of skin diseases, and 17 of painful affections of the muscles.—*The Lancet.*

Distribution of Tubercle Bacilli Outside the Body.—The following are the most important results of Cornet's investigations on this subject: 1. In the dust of rooms of private patients suffering from consumption who were careful always to expectorate into a spitting-cup, and never into a handkerchief or on the floor, tubercle bacilli were *never* found; if, on the contrary, they expectorated into a handkerchief or on the floor, bacilli were *always* present in the dust. 2. The dust of most consumptive wards in hospitals contained tubercle bacilli. 3. The air of two policlinics, of a theatre in a pathological institute, of the dormitory in an orphan-house, of several streets, and of several public buildings, was found free from bacilli. Tubercle bacilli are incapable of multiplying and flourishing except in the tissues of men and other animals. Many cases of tuberculous disease are due to the ingestion of bacilli in meat, and especially in milk; but in most cases of consumption the virus is derived from other consumptive patients. The breath of such patients does not contain bacilli—the sputum is the means of infection. From moist sputum bacilli can never get into the air; it is when the sputum becomes dry and is converted into a fine powder that it is dangerous. It can easily be understood that as long as the sputum is expectorated into a spitting-cup the danger of infection is slight; but if the sputum is deposited on the floor or in handkerchiefs, towels, etc., it soon dries, and movement and friction—*e.g.*, shaking and using the handkerchief—readily convert it into powder which can float about in the air. When sputum is expectorated in the open air, as in streets, the danger of infection is slight. Rain and damp weather keep the sputum moist and harmless; and if it does dry and become pulverized the winds dilute it to an infinite degree and blow it away. The practical rules which Dr. Cornet lays down are: Consumptives should never expectorate into a handkerchief or other cloth, or on the floor, but should always use a suitable spitting cup, in which some fluid may be kept in order further to prevent the chance of drying. If expectoration into a handkerchief is ever unavoidable, the handkerchief should be at once boiled and washed. Consumptives should not be kissed; if this must be, the forehead or cheek should be chosen rather than the mouth. Spoons, glasses, etc., used by consumptives should be carefully cleaned.—*The Dublin Journal of Medical Science.*

tion, incessant cough, night-sweats, loss of appetite, and much general debility. He being over sixty-two years of age, I hesitated to undertake the treatment, and yielded only to his persistent request. I directed him to a neighboring hotel, where I injected the cavity with the pulmonary fluid which I had been in the habit of using, and the result was eminently satisfactory. My friend Dr. J. Lee Morrill very kindly offered me his aid in the operation, having previously verified the diagnosis. The operation was followed by no unpleasant reaction, and the next day the patient visited some friends out of the city.

The second day after the operation he walked to my office from the Long Island Ferry, East Thirty-fourth Street, a distance of two miles, declaring that he felt no

LUPUS AND THE LYMPH.

Now that a considerable number of lupus cases are under treatment in the various institutions of this city, it has been noted that the results of the lymph inoculations are quite marked, and apparently much benefit has resulted to those experimented upon.

The question of the nature of lupus is of growing interest and importance. It is a very noticeable fact that, although in almost all the recent writings and discussions of the subject lupus is treated of as a disease identical with tuberculosis of internal organs, little or nothing has been said against this view. As we have already mentioned in these columns, the theory is one which has not received universal acceptance. In a paper read at a meeting of the American Dermatological Association, some years ago, Dr. Hyde, of Chicago, took decided grounds against the idea that lupus is a disease chiefly associated with tuberculosis, but that it is a local infection having no connection with any constitutional diathesis. For this belief he advanced the following grounds:

1. The unimpeachable character of the family history in by far the larger number of cases of lupus vulgaris. 2. The fact that the disease is in its inception a disease of the period of childhood, when, for the most part, the habits of the child are favorable to infection. 3. The several sites of predilection are those most favorable to such infection (local). 4. The failure of the disease to spread by inheritance. 5. The remarkable tendency of lupus vulgaris to cutaneous limitation.

On the other hand, at the International Congress held at Copenhagen, Professor Doutrelepont maintained that lupus is really a tuberculosis of the skin. He was opposed at this time by Kaposi, who, during a twenty years' experience, had seen one thousand two hundred cases of lupus, and had never noticed any connection between it and tuberculosis. Many of those at the present day who believe that lupus and tuberculosis are not identical diseases, still admit that there must exist an intimate relationship. If the bacilli found in the two processes are not the same, they must be at least first-cousins, and the experimental treatment now in progress, if it does not prove positively and permanently curative, may at least serve to clear up these disputed points.

Reported cures of lupus have already been made, but keeping in mind the well-known tendency of the disease to recur, we should not be more hasty in pronouncing a given case cured under Kochine, as the lymph is now facetiously called, than after treatment by the older methods. Time, and time alone, will prove the cure, and this is quite as true of lupus as of phthisis.

THE LIMITATIONS OF THE CURATIVE LYMPH.

IT is now over three months since Professor Koch began the experiments with his lymph upon man. This is almost a sufficient time to determine whether consumption in its earliest stages can be cured. Professor Leyden has treated 127 cases, Dr. Guttmann 75 cases, and Professor Gerhardt 79 cases. All these are, in addition to the cases first treated, directly under Koch's supervision. Among these 281 cases we hear of four deaths, while Dr. Guttmann announces four cures. Most of the remaining cases are simply "doing well."

If any experienced physician were to treat 281 cases of phthisis in the very initial stage by methods already known there is very little doubt that much better results could be obtained, even within two or three months, than a simple one per cent. of cures. So far, therefore, it must be conceded that Koch's lymph has shown no special remedial power against pulmonary tuberculosis. There is a belief that it is more effective against laryngeal tuberculosis, but we hear as yet of no announced cures.

Its specific effect upon lupus is, so far, quite interesting. Temporary "cures" have certainly been produced by it.

The severest criticisms upon the action of the lymph come, naturally perhaps, from the Paris physicians. Pasteur is quoted as saying:

"Up to this moment there has not been a single authenticated cure, not even of lupus. Dr. Bergmann himself has seen a patient suffering from lupus return to his hospital fifteen days after having been discharged as cured, a severe relapse having occurred even within that brief interval. Moreover, there is no real certainty as to the consequences of the treatment. The medicament is of unheard of virulence, and the reactions which it brings on are terrible. No venom from a snake, if administered in such small doses (two tenths of a milligramme), could cause such results. We have therefore a toxic of such indomitable energy that it may introduce into the organism disorders the consequences of which no one can surmise, and have yet to be studied. You may have seen a report in the medical papers of yesterday that albuminuria and hæmaturia have been found in a patient who had been treated for tuberculosis to very small doses of this lymph. In fact, it is the kidneys that are particularly affected by it."

Pasteur, referring to the early publicity given to Koch's method of cure, says in conclusion:

"Whatever happens, you may be perfectly certain that the École Bactériologique Française will not imitate their example. So long as the results of its investigations are unascertained we shall be silent. So soon as a single point shall have been perfectly established we will report the fact in detail to the Académie de Médecine."

HYPNOTISM AND CRIME.

THE extraordinary criminal case which has recently been before the Paris courts has aroused much discussion as to whether a person can be hypnotized and made to commit a crime. The accused persons were the man Eyraud, and his mistress, Bompard. The latter enticed a wealthy man into her rooms where her lover was concealed. The two murdered the man, put his body in a sack, the sack in a trunk, took the murdered man's money, and left the country. The man confessed the crime, the woman, it is said, under hypnotic influence, also confessed, but pleaded subsequently that she was under her lover's hypnotic influence, and could not help herself. Her counsel put in this plea on her behalf before the court, and secured the services of Professor Liegeois, of Nancy, and of her family physician. The latter testified that he had frequently hypnotized her and compelled her to do various acts at his suggestion.

Professor Liegeois made a long, set speech in favor of the hypnotic theory. Professor Brouardel and Dr. Mottet denied the possibility of her or anyone else being forced to do a complicated and criminal act under hypnotic suggestion.

The controversy developed apparently into one of "schools," rather than of facts. It was the Nancy school pitted against the Salpêtrière and Charcot school.

The jury decided that the woman was responsible, but found extenuating circumstances, and she was sentenced to twenty years of hard labor. Paris and Nancy came off, therefore, about evenly in the matter of hypnotism.

The question of hypnotism and crime has several times been brought up in this country by Dr. William A. Hammond, the late Dr. Beard, and others. It is possible that simple acts, such as forging or signing the name to documents, or doing some violence, may, in rare cases, be brought about by hypnotic suggestion. The combination of circumstances, however, which would permit of this is very rare indeed.

No one could be forced by hypnotic suggestion to do complicated acts, involving judgment, discretion, and adaptation of the actions to new or unexpected circumstances.

THE RATIONAL TREATMENT OF PNEUMONIA.

THE medical profession hears with languid interest of reports of new and curative drugs in pneumonia. When, however, an ingenious, logical, and sensible application of known physiological data is made to the therapeutics of this disease a more scrutinizing attention is called for. An article by Dr. Andrew H. Smith, on "Acute Obstructive Diseases of the Lungs" (*American Journal of the Medical Sciences*), has all the characters just mentioned. Dr. Smith shows that in an obstructive lung disease like pneumonia, it is the right heart that bears the chief burden. The physician ought, therefore, to watch it with even more care than the radial pulse. The pulmonary aortic pulse cannot be felt, but its strength and that of the right heart can be gauged by the intensity of the pulmonary aortic valvular sound.

In an obstructive pneumonia the blood is dammed back into the veins, and there is venous congestion, while the arteries are not full enough.

The therapeutist should aim, therefore, to distribute the blood more evenly. This may be done by taking away blood from the veins by venesection. But a safer method is to use such drugs as nitro-glycerine and the other nitrites. Alcohol is also thought to be of great value, not only as a general stimulant and food, but as an arterial depressor. Dr. Smith asserts that too much food, especially liquid food, should not be given to pneumonia patients, as this embarrasses digestion and fills up the circulatory system with fluid.

Oxygen gas and artificial respiration are also recommended, to be used even before the patient's condition is critical.

Digitalis should not be used in most cases of pneumonia. This is a dictum supported by good authority and large experience. Yet digitalis continues to be given.

Dr. Smith's contribution to the therapeutics of pneumonia is the best that has been made for years. Yet he makes no allusion to antipyretics or baths. His conclusions are given as follows:

1. In acute pulmonary obstruction, the danger being from exhaustion of the right heart, the pulse at the wrist does not give reliable indications as to the gravity of the condition.

2. This can be appreciated more correctly by studying the pulmonary circulation by the aid of the pulmonary valve-sound.

3. Marked accentuation of the pulmonary valve-sound indicates a fairly vigorous right heart laboring to overcome resistance in the pulmonary circulation.

4. Decrease of a previously existing accentuation, with only moderate dyspnœa, indicates decrease of pulmonary obstruction.

5. Decrease of accentuation, with increase of respiratory distress, indicates that the right heart is becoming exhausted.

6. Relief is to be sought: *a*, by regulating the diet in conformity with the diminished power of digestion and sanguification; *b*, by the use of medicines which dilate the arteries and promote transferrence of blood to them from the veins; *c*, by the inhalation of oxygen gas; *d*, by artificial respiration; *e*, by placing ligatures about the extremities in order to retain the blood in them and prevent its return to the heart.

Sulphonal in Diabetes.—Dr. Casarelli, of Pisa, mentions the favorable action of sulphonal in diabetes (*Lancet*). This drug diminishes the quantity of sugar in the urine, also reducing the polyuria and the thirst. These results were obtained by doses of from 5 to 30 grains per diem, but not to so marked a degree as with doses of 45 grains continued for several days. The 30-grain doses could be administered for some time without any ill effects; but although the 40-grain doses at first caused no disturbance, it was found that, when they were continued for any lengthened period, they caused giddiness and excessive sleepiness, which disappeared when the drug was discontinued.

News of the Week.

The Claimants for Priority in the discovery of a curative lymph have been put in a hard plight by the fact that they do not know yet what the lymph is. If a formula were given containing any known substance in heaven above or earth beneath, we should certainly be told that Dr. X——, of Blank, had used and recommended this years ago, and had cured many cases with it. As it is, we have only heard of two claimants, a Paris physician who uses injections of eucalyptol, and a New York physician, now deceased, who used some preparation from tuberculous tissues.

There is One Feature connected with Koch's recent discovery which ought to have a moral and didactic value to our countrymen. It is the spectacle of a man giving to the world a discovery which, if patented or even turned into a business venture, would bring to him untold millions. However much we may regret the secrecy maintained regarding the composition of the lymph, no one believes that it is for any selfish or commercial reasons that this secrecy is maintained. Koch declares his desire to turn over the manufacture to the National Government which will distribute it for the benefit of the human race.

Dr. Liebeault, of Nancy, the father of suggestive therapeutics and the scientific application of hypnotism to medicine, is about to retire from practice. A committee has been organized by some of his pupils for the purpose of raising a fund to present to him as a testimonial of regard for his character and work. Dr. Lloyd, of London, is Secretary.

Koch and Kotch.—It would really be a service to orthoëpy and morals, and a blow to vulgarity if the term "Koch," or the term "lymph," were dropped in lay journals. At first the un-German world were prone to speak of "Kotch's lymph," and "Kotch's discovery." Since it is learning that the *ch* is hard and still harder to pronounce, it would be better to say the curative lymph or the parataloid, if that is the term Professor Koch desires.

The Department of Charities and Correction of this city asked for $3,115,705, but were allowed only $2,100,137. This is a severe and apparently uncalled-for cutting down of medical appropriations. The department is a very large one and has a class of unfortunates, the sick and insane, under its care, whom the public think ought to be treated with particular consideration.

Guarding the Public Health.—Our Western brethren in Indiana are going to be sanitary or nothing. The State Board of Health has "requested" the owners or managers of all railroad coaches and street cars carrying passengers in this State to provide storm-doors or vestibules for each car designed to carry passengers. Thermometers must also be provided for each car, and the temperature kept at 68° or 70° above zero. Perfect ventilation must also be had. Spittoons must be provided, and the conductor required to see that one shall be partially filled with a solution of bichloride of mercury, and placed near the seat of any passenger suffering with chronic cough and expectoration, and that such person shall be directed to use the spittoon and not the floor. J.,

A New Hospital Wanted for Italians.—Appeal is made for funds to start an Italian hospital in the city. It is a question, however, whether we have not hospitals enough for the present. If the Italian colony here would hire interpreters for the various existing city hospitals, it could accomplish a charitable work for very much less money than would be required for a new hospital.

Dr. A. T. Augusta, a prominent colored physician of Washington, D. C., died on December 21st.

Inspection of Immigrant Cattle.—The United States is very particular about its cows. It lets in half a million men and women, mostly of the scum of Europe, annually, without asking any questions; but not a cow, or pig, or sheep can come in or go out without a rigid inspection. The Department of Agriculture has just established a bureau in this city under charge of Dr. Mitchener and eight assistants, their duties being to inspect the exported and the imported cattle.

Northwestern Dispensary.—At the twenty-second Annual Meeting of the Northwestern Medical and Surgical Society the following officers were elected: *President*, Dr. S. Henry Dessau; *Vice-President*, Dr. Edward S. Peck; *Secretary*, Dr. Frank Graner.

Dr. E. C. Wendt is using the Koch lymph (obtained through the courtesy of Dr. L. Weber) in his service at the New York Infant Asylum and at the St. Joseph's Asylum.

A Remedy for the Abuse of Medical Charity, suggested by Dr. Gould (*Medical News*), is that a codicil to all wills and bequests be prescribed, worded in such a manner that, unless the trustees of the institutions named exercise stringent care that only truly needy persons receive the benefit of the bounty, the bequests shall revert to the heirs.

Instruction in Abortion.—The *Medical and Surgical Reporter* says that it has received a pamphlet which is evidently being widely distributed. This pamphlet offers for sale a translation of a book by Velpeau, in which instructions may be found how to produce abortion in a variety of ways, some of which are "not known to the medical world," and also "valuable hints as to the best means by which evasion of the law can be accomplished when a physician is so unfortunate as to be 'suspected' of having been guilty of the step."

tation of Alexander Mott and other leading physicians.

A Royal Teetotaller.—The King of Samoa is determined that his subjects shall be sober, if they are not free. He has just issued a proclamation to the following effect: "No spirituous, vinous, or fermented liquors, or intoxicating drinks whatever, shall be sold, given, or offered to be brought or bartered by any native Samoan, or Pacific Islander resident in Samoa, to be taken as a beverage." Any breach of this law is to be visited with heavy penalties.

California Medical Colleges.—The Cooper Medical College of San Francisco held its commencement exercises November 13th, and conferred degrees upon a class of twenty. The Medical Department of the University of California held its commencement on November 20th, and graduated a class of thirteen.

"Rizzling" as a Therapeutic Agent for Indigestion and Nervousness.—"Rizzling" is a new term in therapeutics and everywhere else. It is thus explained by a physician, who states that it is the most wonderful aid to perfect health. "I masticate my food very thoroughly at dinner," he says, "and make sure to have my family or friends entertain me with bright talk and plenty of fun. After dinner it is understood that I am going to rizzle. How do I do it? I retire to my study, and, having darkened the room, light a cigar, sit down and perform the operation. How to describe it I don't know, but it is a condition as nearly like sleep as sleep is like death. It consists in doing absolutely nothing. I close my eyes, and try to stop all action of the brain. I think of nothing. It only takes a little practice to be able to absolutely stifle the brain. In that delightful condition I remain at least ten minutes, sometimes twenty. That is the condition most healthful to digestion, and it is that which accounts for the habit animals have of sleeping after eating. I would rather miss a fat fee than that ten minutes' rizzle every day."—*Chatter.*

A New Cure for Spasm of the Glottis.—Spasm of the glottis is notoriously a very alarming condition, and one which it is often as difficult to relieve as the circumstances are urgent. Sir Morell Mackenzie gives a good "tip," and one worth remembering. The spasm is the result of a reflex, the starting-point of which varies in different cases, and he has found, as the result of experience, that a pinch of snuff, judiciously sniffed up the nostrils, will, by exciting another and violent reflex, cause the former to subside.

Number of Patients under the Koch Treatment.—On the first of this week there were under treatment at the hospitals in this city 116 patients. Mount Sinai Hospital has 29; the Montefiore Home, 21; the German Hospital, 19; St. Luke's, 17; Bellevue, 11, and St. Mark's, 9.

The Cradle of Influenza.—Professor Tessier, of the medical faculty of Lyons, has returned from Russia, whither he was sent last March to take evidence upon the course of influenza there and the various conditions of its evolution. He found that influenza is a growth of Russian soil, and when not a raging malady is a smouldering one. The way the people live in winter, locked up in heated houses; the flatness of the soil, its consequent bad drainage and [illegible] OF PNEUMONIA.

THE medical profession hears with languid interest of reports of new and curative drugs in pneumonia. When, however, an ingenious, logical, and sensible application of known physiological data is made to the therapeutics of this disease a more scrutinizing attention is called for. An article by Dr. Andrew H. Smith, on "Acute Obstructive Diseases of the Lungs" (*American Journal of the Medical Sciences*), has all the characters just mentioned. Dr. Smith shows that in an obstructive lung disease like pneumonia, it is the right heart that bears the chief burden. The physician ought, therefore, to watch it with even more care than the radial pulse. The pulmonary aortic pulse cannot be felt, but its strength and that of the right heart can be gauged by the intensity of the pulmonary aortic valvular sound.

Jews have Cancer also.—Dr. John C. Hupp. of Wheeling, West Va., writes: "The assertion of one of the lecturers at Owens College, Manchester, quoted from an English paper in your issue of December 6, 1890, page 637, 'that no Jew or Jewess has ever been known to suffer from cancer,' is not correct. Three Jewesses have come under my observation suffering from cancer: two of these died 'suffering from cancer;' one lives minus her left mammary gland."

The Doctor is often a preacher of morals, but in "Every-day Etiquette," a recent work by Dr. Fisk Bryson, of this city, he, or rather she, becomes a preacher of manners also. Dr. Bryson's book is clever and sensible; and infuses into every day etiquette just enough anatomy and physiology to show that there is a physical as well as moral basis to good manners.

A California Physician has let loose the statement that "American medical men do others as others do them." This ingenious perversion and individual appreciation of the second commandment has excited an active controversy in the *Occidental Medical Times*, out of which we trust much good will grow.

Sulphur.—Professor Boudard's views fit in not only with my grandmother's practice, but also with the dictum of the late celebrated Dr. Budd, of Plymouth, who used to say, according to the local gossips, that sulphur was the best medicine in the Pharmacopœia of his day, and that if it were a guinea an ounce more would be taken.—*Hospital Gazette.*

Chocolate Inebriety.—A chocolate inebriate has appeared. His addiction has been for three years, and his general health is much impaired, principally the digestion. His only thought night and day is how to get chocolate.

A Boston Theory.—The prevalence of earache and neuralgia among women and children this year is attributed by a well known doctor in town to the draught which is created between the face and the high sleeves now in vogue.

Women Doctors in Germany.—An association of German women, at a meeting a short time ago, passed a resolution agreeing to a petition being presented to the German governments, praying for permission to be granted to women to study medicine. The petition so far has been flatly refused by Prussia, Würtemberg, Saxony, and the Duchies of Hesse-Darmstadt and Saxe-Weimar. This is not surprising in view of the hyper-congested condition of the medical profession in the fatherland.

Suicides in France.—In France, from 1827 to 1880, about two hundred thousand persons committed suicide. Of these, over fifteen thousand men and eleven hundred women were inebriates, and intoxicated at the time of death.

Our Contemporary, the Post-Graduate, comes to us under a new management and with very entertaining contents. It is made up largely of accounts of the International Congress, by various professors in the school, who give their personal experience and impressions regarding the work of the sections of surgery, medicine, dermatology, ophthalmology, neurology, etc.

The Hand of Esau and the Voice of Jacob.—Dr. W. E. Forest writes: "In the report of the meeting at the New York Academy of Medicine, of December 4th, given in your journal of the 13th instant, your reporter by mistake ascribes remarks, under the head, 'A New Form of Artificial Respiration,' to Dr. A. S. Hunter. The credit for these remarks, if they are worthy of credit, should be given to myself. In conversation with your reporter I learn that he made the mistake through thinking that my voice was that of Dr. Hunter, and thus did not look up from his writing to see that the speaker was 'a younger and a handsomer man' than is my friend Hunter. A very similar mistake occurred some time ago, when our ancestor Isaac gave the blessing to the wrong son, reported in Genesis xxvii. 22. 'The voice is Jacob's voice, but the hands are the hands of Esau.'"

Hospital Graduates' Club.—The following officers have been elected: *President*—Dr. Nelson H. Henry; *Vice President*—Dr. James E. Newcomb; *Secretary*—Dr. T. T. Janeway. This is one of the most prosperous of the younger medical clubs. A full term of service in a recognized hospital is a prerequisite for membership, and we learn that this idea is being followed by hospital men in other cities.

A Widows' and Orphans' Society in Philadelphia.—Dr. Henry Tuck, President, and Dr. Gouverneur M. Smith, late President of the New York Society for the Relief of Widows and Orphans of Medical Men, by invitation of the Physicians' Mutual Aid Association of the Philadelphia County Medical Society, addressed that association on Wednesday evening, December 10th, explaining the operations of our New York Society. After the meeting the members gave a reception at the University Club to Drs. Tuck and Smith, and also to Professor Roswell Park, of Buffalo, who had lectured in the Mutter course.

The xl. was Written like xii.—Dr. Julius Rosenberg writes: "Will you oblige me by correcting a few errata which are contained in my article on 'Fuchsine,' published in the last MEDICAL RECORD. The fuchsine contained in each solution should be grs. xl. (40), instead of grs. xij. (12), and solution No. II. should contain—aquæ, ℥ xv. (15)."

The Supply of Koch Lymph for New York is still limited, notwithstanding the reports to the contrary. Its use is so strictly confined to the different hospitals here that, for the present at least, it will be vain for medical friends in distant parts to hope for the coveted fluid. Those gentlemen who have the fluid in charge are under restrictions not to use it, or allow it to be used, outside of their wards, or without their direct supervision. This is in order to guard against accidents with private patients, who cannot be constantly under the eye of a medical man. Urgent and suitable cases can be treated in the hospitals, and in no other way. In the course of the next month it is expected that a sufficient quantity of the lymph will arrive, not only to abundantly supply all the hospitals here, but others in the principal cities.

Society of the Alumni of Charity Hospital.—At the meeting of the Society of the Alumni of Charity Hospital, held December 9, 1890, Dr. Newton, of Montclair, N. J., presented a specimen of supposed myxo-adeno sarcoma from the uterus of a woman eighty-two years of age. Dr. Brooks Hughes Wells read a paper on peri-uterine inflammations, in which he took the ground that no man should be allowed to marry while suffering from even the slightest gleet, because of the danger of infecting his wife and lighting up pelvic trouble. An animated discussion followed, which was participated in by Drs. Clemens Cleveland, Bryson Delavan, J. B. Bissell, W. L. Carr, and others. The following officers were elected for the ensuing year: *President*—Bryson Delavan, M.D.; *Vice-President*—Ramon Guitéras, M.D.; *Secretary*—D. E. Walker, M.D.; *Treasurer*, A. T. Muzzy, M.D.

An Aseptic Operating-room.—Dr. E. B. Thompson, of Marion, Ala., suggests a new idea for an aseptic operating-room. Within a well ventilated and lighted room of thirty by forty feet is constructed a small glass room of ten by twelve feet. The room to contain only the things absolutely necessary for the operation; solutions to be drawn by pressing a button, and purified air for respiration to be forced in through tubes. By a portcullis arrangement of door he would have gynecological cases admitted to the chamber only so far as the part to be operated upon, the space around the patient to be closed by the outside assistants.

No Doubt About It.—"You think there never was another baby like yours, don't you?" said the cynical old doctor to the young mother. "No, doctor," replied the young mother, reproachfully, "I don't think so; I know there never was."

Our Legless Population.—It is estimated that there are about three hundred and fifty thousand persons in this country with only one or with no legs. Many lost their limbs in the war, but since that time the great amputator is the railroad. Ninety per cent. of amputations are chargeable to the railroad, according to a writer in the *Times*, who also states that among 4,056 cases of loss of limbs reported in the daily papers, in six months, 3,500 were railroad cases.

Dr. Joseph Edward Ralph died at Canarsie, L. I., on December 9th, aged seventy-three years. He came to this city from England fifty years ago, with his father, Dr. Joseph Ralph, who established himself here at the solicitation of Alexander Mott and other leading physicians.

A Royal Teetotaller.—The King of Samoa is determined that his subjects shall be sober, if they are not free. He has just issued a proclamation to the following effect: "No spirituous, vinous, or fermented liquors, or intoxicating drinks whatever, shall be sold, given, or offered to be brought or bartered by any native Samoan, or Pacific Islander resident in Samoa, to be taken as a beverage." Any breach of this law is to be visited with heavy penalties.

California Medical Colleges.—The Cooper Medical College of San Francisco held its commencement exercises November 13th, and conferred degrees upon a class of twenty. The Medical Department of the University of California held its commencement on November 20th, and graduated a class of thirteen.

The Struggle for Existence in the Profession.—While so many gloomy things are being uttered by amateur social scientists, respecting the struggle for existence, it is pleasant, says the *British Meaical Journal*, to read the following words of a great American physician, Dr. Jacob Bigelow, the nonagenarian, father of the eminent surgeon recently deceased. "I have an unqualified belief," said he, "that by far the most happy form of life is that which proceeds through difficulties to success, and in which the candidate, after beginning at the bottom of the ladder, finds himself to be a little raised in position, ability, and usefulness during the successive years of his life. In this way only does he appreciate the value of little acquisitions and of small advances in the social scale. Difficulty is the best antidote for satiety, and is needed by multitudes who begin life in the early possession of things for which others must wish and labor and wait." These words are recorded in Mr. G. E. Ellis's "Memoir of Jacob Bigelow, M.D."

Grafting the Thyroid for Myxœdema.—The operation of grafting the thyroid in a case of myxœdema has again been performed with success. The patient was shown by M. Merklen, at a recent meeting of the Société Médicale des Hôpitaux in Paris; the thyroid graft was taken from a living sheep at the time of the operation; no antiseptics were used, but the graft and wound were kept carefully aseptic. Healing occurred by first intention, and the patient, a woman aged forty-one, improved considerably. The improvement appeared to be due in great part to the arrest of metrostaxis, from which the patient had previously suffered for months at a time; the hemorrhage ceased three days after the operation, and had not recurred when the report was made, three months later. The swelling of the face had decreased, the pseudo-lipomata diminished, and the mode of speaking became more natural. The graft, which consisted of one of the lobes of the gland, was inserted beneath the skin in the right submammary region.—*British Medical Journal.*

The Operation of the Removal of the Gasserian Ganglion for tic douloureux, has recently been done by Professor William Rose, of London. The patient's eye was lost on the affected side, but the neuralgia ceased. This is said to be the first instance in which such an operation has been done.

Quinine and the American Girl.—There are very few freaks of nature which quite come up to the American girl, if one may judge by the statements found in current European literature. One of the latest outbreaks of the feminine American fancy is the quinine habit. "American girls," says the *British Medical Journal*, "now carry about with them ornamental cut-glass bottles containing quinine pills, with which they dose themselves from time to time. If fatigued they take two pills; if chilly, one; if hungry (as they generally seem to be), four or five. We believe that ten is the correct dose for wet feet. The quinine bottle is equal to every emergency, and produced on all occasions. We are glad," adds the *Journal*, "it is no worse than quinine; at one time it used to be morphine and strychnine pellets; it might even now be ether."

THE KOCH TREATMENT IN NEW YORK.

CASES AT ST. LUKE'S HOSPITAL.

SERVICE OF DR. FRANCIS P. KINNICUTT.

At the end of the second week of investigation of the treatment of tubercular disease by inoculation with Koch's lymph, in the wards of St. Luke's Hospital, the first profound impression made upon the observers of its potency and elective affinities have only been strengthened.

As a thorough clinical study of a larger number of cases would be impossible, only seven new patients have been inoculated, making the total number of cases at present under treatment twenty-two. The new cases are as follows: one case of aggravated eczema of the hands, orbicular in form, inoculated as a control experiment; one case of lupus of the uvula and contiguous portions of the throat; One case of tubercular glands (cervical and submaxillary), with doubtful signs of infiltration at the apex of one lung; one case of epithelioma of the hand, inoculated with the view of studying the possible effect of treatment; one case of tubercular disease of the ankle-joint; one of hip-joint disease; and one of pulmonary tuberculosis in its incipient stage.

The rule has been maintained of making use of 0.001 gm. for the initial inoculation in adults, of 0.0005 gm. in children. The rule is also adopted of continuing the same dosage until reaction ceases to be developed; of increasing its strength by 0.0001 gm. successively as reactions cease to appear. In cases of lupus, Koch's suggestion that inoculations be given at intervals of a week or longer, that is, only after local reaction has subsided, is now followed.

The observation has been made that the systemic disturbances in this disease are less severe than those exhibited in other forms of tubercular disease, the inoculations being of similar strength. Inasmuch as the reaction in several instances has been delayed as late as twenty-four hours, and has then been characteristic, daily inoculations are not given in any instance. Local irritation at the site of inoculation has not occurred in any of the cases.

The possibility of obtaining equally good results with a smaller amount of lymph than that used by the German investigators has apparently been demonstrated; 0.004 gm. for a single inoculation has not been exceeded up to the present date in any instance. By this method, moreover, it seems that the distressing, if not grave, symptoms of very acute reactions may be avoided. The marked systemic disturbances, aside from the rise in temperature, in a number of patients treated with small doses, has been impressive, and has suggested caution in treatment.

The appearance and condition of the patient during the period of reaction, in many instances, has been suggestive of the presence of an acute infectious disease. A low arterial tension has obtained, as a rule. No increase in the area of splenic dulness has been appreciable in any instance after inoculation.

Characteristic reactions have been obtained in all cases, with the exception of the one mentioned in the previous number of the RECORD,[1] and the case of eczema. In the latter no constitutional or local reaction occurred.

The local changes observed in the remaining cases of lupus correspond very closely to those described in the case whose history is appended. In all the patients suffering from pulmonary tuberculosis the present physical signs indicate a more extensive area of infiltration than was suspected. The local signs in the cases of bone tuberculosis have been of the greatest interest. The records, subsequent to the third inoculation, of the three patients whose histories were given in the last number of

[1] The inoculation in the case of epithelioma of the hand was made too late to state the result at the present hour.

the MEDICAL RECORD, are appended. The history of a case of incipient hip-joint disease has also been selected as presenting points of especial significance.

CASE I. (of previous report). *Tubercular Infiltration of Apex of Right Lung.*—Re-inoculations, 0.001 gm., were made on the 20th and 22d, the reactions being very similar to those previously described. The physical signs observed at the present date differ very materially from those present prior to the first inoculation. They consist in a distinct increase in the moist crepitation, which is heard over a decidedly larger area, associated with large mucous râles, and an extension of the limits of bronchovesicular respiration. The inference is that the tubercular infiltration is more extensive than was appreciable by physical signs.

CASE II. (of previous report). *Prostatic Surface Tubercular Disease.*—Inoculations 0.001 gm. were made on December 19th and 22d, with the development of reactions very similar to those previously obtained. The only appreciable difference in the patient's symptoms prior to the first inoculation, and at present, consists in the greater freedom from pain in the urethra on passing urine.

CASE III. (of previous report). *Lupus Vulgaris of the Ear and Contiguous Portions of the Face and Neck, of Twelve Years' Duration.*—Last inoculation, December 16th, 0.003 gm. It was deemed advisable to permit all local reaction to subside before further inoculations, and none have been made since. The present appearance of the diseased tissues is described by Dr. George H. Fox, as follows: The crusts having been removed by the application of cotton wool in oil, the affected area appears red and smooth, and the cicatricial lines from previous scarification are again apparent. There is less appearance of lupus infiltration. The whole ear is softer to the feel; this is especially true of the lobe, which, aside from the presence of hyperæmia, has a normal look and feel.

CASE IV. *Incipient Hip-joint Disease.* — Female, aged six, in the service of Dr. Newton M. Shaffer, at the New York Orthopædic Dispensary, from November 9, 1890, until admission to St. Luke's Hospital.

Previous history: Patient had been noticed to limp for three weeks, and had had "night cries" for about the same period.

Examination: Characteristic limp, attitude, and reflex muscular protection of the joint present; although these signs were not of the most pronounced type, a diagnosis of incipient hip-joint disease was made by Drs. Samuel Ketch and Newton M. Shaffer, after a very careful examination. A long traction splint was applied.

Admitted to St. Luke's Hospital December 17, 1890. Dr. Shaffer, by my request, has very kindly made daily examinations of the patient, and all further reports of the joint signs are given in his own words. Examination by Dr. Shaffer immediately before first inoculation. Patient has no pain, walks with a perceptible limp, the thigh being slightly flexed in locomotion. Examination of joint shows no perceptible swelling. The inguinal fossa on right side not quite so pronounced as on left. Concussion of the hip joint gives no pain. There is no deformity present, the flexion above noted disappearing when the patient is recumbent.

The tests, as applied to the movements of the hip, resulted as follows: Flexion markedly resisted about 10 degrees short of full flexion. When this point is reached the patient flinches very decidedly, as is also the case in abduction and adduction of the thigh, both these movements being limited by reflex muscular spasm a few degrees short of normal. With the thigh flexed to about 135 degrees rotation *in* is very markedly resisted. Rotation *out* in same position resisted only in the extreme. With patient prone, extension of thigh (pelvis being held firmly) quite noticeably resisted. In this position, both rotation *in* and rotation *out* were very much restricted. In all these tests the patient flinched very plainly when it was attempted to pass joint beyond the point indicated by the instinctive muscular protection.

First inoculation, December 17, 1890, 3.30 P.M. Temperature normal; 0.0005 gm. Reaction developed eight hours later. Duration of reaction, thirty-seven hours. Highest temperature, 103° F.

Examination, December 18th, twenty four hours later. Hip-joint in position characteristic of hip joint disease in the second stage—that is, the thigh is abducted, apparently elongated, flexed and rotated outward. The joint is very sensitive, the slightest attempt at motion giving pain. By using great care 10 degrees of lateral movement (in abduction and adduction) can be demonstrated. There is a movement of flexion of only 15 degrees. No rotation can be demonstrated. The inguinal fossa is obliterated, and there is œdema of posterior swelling. The deformity present was as follows: Thigh flexed at 150 degrees; abduction, 20 degrees; rotation out, about 30 degrees.

The following peculiar condition was noted, unlike that found in morbus coxæ, in the acute stage. The patient noticed no difference between crowding the joint surfaces together and on making traction on the joint. Each test produced pain, and there was no relief from traction.

December 19th. Joint movements much changed for the better; all movements of the joint can now be made, but they are still greatly restricted.

Deformity: Flexion 160 degrees; abduction nil. Rotation in and out still restricted.

Rotation in gives pain. Patient still notices no difference between pressure and traction upon the joint; swelling still present.

December 20th. Joint movements very much like those of yesterday. The same may be said of the deformity. Joint can be handled with much more freedom. Inguinal fossa still obliterated.

Second inoculation, December 20th. Temperature normal; 0.0005 gm. Only a very slight reaction developed eleven hours later. Duration of reaction, eighteen hours. Highest temperature, 100° F.

Examination, December 21st, twenty-four hours later. Motion in joint is more free than yesterday, except in adduction, which can be made of 5 degrees. Rotation still being limited. Inguinal glands can be made out. Deformity: Flexion, 155 degrees. Rotation out, unchanged. Muscular resistance at joint well marked. Tenderness of joint diminished.

December 22d. Examination at 5 P.M., Dr. Thomas L. Stedman being present. The following movements of the joint are normal, viz.: Flexion, adduction, and rotation out; rotation in, extension, and abduction are approximately normal; rotation in during flexion is slightly resisted. Another important condition was noted at the examination: The character of the muscular resistance is unlike that observed at the examination of December 17th.

The peculiar instinctive muscular check which accompanies hip-joint disease, and which was noted on December 17th, has disappeared. The muscular resistance to-day can be overcome by gradual and gentle pressure, without pain or flinching, and that which appears to be a fixed resistance to joint movement disappears. The joint can be handled with freedom without inflicting any pain. Still some swelling in inguinal fossa.

There are four points that seem very instructive: 1, the diagnostic value of the lymph; 2, the immediate and extraordinary changes produced in all the signs and symptoms by inoculation; 3, the fact that although the joint was acutely painful, traction gave no relief; 4, the great change in the character of the muscular protection to the joint.

It was deemed best to use the long traction splint during the treatment, and the immobilization produced by it was of great comfort to the patient. The future history of the patient will be watched with great interest.

AT ST. MARK'S HOSPITAL.

REPORT OF CASES TREATED AT ST. MARK'S HOSPITAL FROM DECEMBER 11TH TO DECEMBER 22D.

CASE I. *Phthisis.*—W. P——, aged fifty-four, waiter. Bilateral tuberculosis of the apices of lungs with occasional hæmoptysis and all other signs of consumption since May, 1890; bacilli in sputum. Disease began after a severe attack of influenza last winter. Daily doses of 0.001 milligramme were followed by the usual reaction of fever up to 102.5° F.; increased expectoration after the fifth injection. The patient's appetite and strength improved considerably. Auscultation now shows increased rales; breathing less harsh.

CASE II. *Phthisis.*—Samuel S——, aged twenty five, Hungarian, cutter. Present illness dates back about five and one-half years, when it commenced with cough, expectoration and night sweats. Cavernous breathing on left side anteriorly; bronchial breathing at right apex posteriorly.

December 15th. 4 P.M.: Temperature, 100.4° F.; injection of 0.002 milligr.; 11 P.M.: Temperature, 98.8° F. Very severe attack of dyspnœa.

December 16th. 9 A.M.: Temperature, 98.2° F.; 4 P.M.: Injection of 0.002 milligr.

December 17th. 5 P.M.: Injection of 0.002 milligr.; 11 P.M.: Temperature, 100.2° F.

December 18th. 9 A.M.: Temperature, 99.3° F., cough increased, also expectoration; 5 P.M.: Injection of 0.002 milligr.

December 19th. 9 A.M.: Temperature, 99° F.; slept better during night, and expectoration is looser and easier; increased appetite; 5 P.M.: Injection of 0.002 milligr.; 11 P.M.: Temperature, 102.4° F.; collapse and dyspnœa.

December 20th. 9 A.M.: Temperature, 98.4° F.; 5 P.M.: Injection of 0.002 milligr.; 9 P.M.: Temperature, 101° F.

December 21st. 9 A.M.: Temperature, 99° F.

December 22d. 9 A.M.: Temperature, 98.2° F.

CASE III. *Lupus.*—Marcus A——, aged fifty one, Hungarian. Present illness dates back about four years; commenced as a very small black speck on tip of nose, and has gradually grown, and now covers half of nose and part of cheeks. It is lupus erythematodes. As it is desirable to show if this form of lupus would be affected by injections of Koch's lymph in a manner similar to cases of "lupus vulgaris," the patient receives the following treatment:

December 18th. 3 P.M.: Temperature, 98.8° F.; 5 P.M.: Injection of 0.002 milligr.

December 19th. 10.40 A.M.: A noticeable difference in the appearance. The region involved by the disease at the tip and on the right side of the nose appeared elevated and reddened and dotted with several whitish blisters. This extended about one centimetre beyond the seat of the affection, while the rest of the nose remained undisturbed. 11 P.M.: Temperature, 97.6° F.; 1 A.M.: Temperature, 97.4° F.; 11 A.M.: Temperature, 98.2° F.; 5 P.M.: Injection of 0.002 milligr.

December 20th. 3 A.M.: Temperature, 97.6° F.; 11 A.M.: Temperature, 98.2° F.; 5 P.M.: Injection of 0.002 milligr.

December 21st. 12.15 P.M.: Injection of 0.002 milligr.; 4 P.M.: Temperature, 100.4° F.

December 22d. 9 A.M.: Temperature, 99° F.; 3 P.M.: Temperature, 99.2° F.

CASE IV. *Phthisis.*—Emma K——, aged forty-nine, two years ago great pain along spine and in lower extremities; the pain in back has continued more or less up to present time. Patient can be up and around sometimes, but is mostly in bed. Has never had any pain in hands or arms. Pain most severe about hips and knees, but not confined to these joints. Lower extremities now much atrophied. Cough and muco-purulent expectorations for about a year. Dulness over right apex anteriorly. Left side, anteriorly, dulness from apex to third rib. Right side, prolonged expiration, increased respiratory sounds. Left side, bronchial respiration, moist rales here and there.

December 11th. Injection of 0.001 milligr.

December 12th. 1 A.M.: Temperature, 104½° F.; 9 A.M.: Temperature, 99° F.; 11 A.M.: Injection of 0.002 milligr.

December 13th. 12 M.: Injection of 0.003 milligr.; 6 P.M.: Feeling of constriction over diaphragmatic region.

December 14th. Copious expectoration; 10.45 A.M.: Injection of 0.026 milligr.

December 15th. 4 P.M.: Injection of 0.002 milligr.

December 16th. 5 P.M.: Injection of 0.002 milligr.

December 17th. 9 A.M.: Temperature, 100° F.; 5 P.M.: Injection of 0.002 milligr.

December 18th. 10.20 A.M.: Temperature, 99.6° F.; 5 P.M.: Injection of 0.002 milligr. Patient feels much better generally; appetite excellent; frequent cough and copious expectoration; 11 P.M.: Temperature, 99.6° F.

December 19th. 9 A.M.: Temperature, 99.8° F.; 5 P.M.: Injection of 0.002 milligr.; 11 P.M.: Temperature, 100° F.

December 20th. 9 A.M.: Temperature, 99.4°; 4.30 P.M.: Injection of 0.002 milligr.; 10 P.M.: Temperature, 100° F.

December 21st. 8 A.M.: Temperature, 99.4° F.; 6 P.M.: Temperature, 100.2° F.

December 22d. 8 A.M.: Temperature, 98.8° F.; 2.30 P.M.: Temperature, 99.6° F.

CASE V. *Phthisis.*—Emma R——, single, United States, seamstress. Present illness began about May, 1890. Commenced with cough, and expectoration. Night-sweats and hectic fever came on in September. Has lost four pounds since August; complains of chills every night the past week.

December 12th. 11.30 A.M.: Injection of 0.001 milligr.; 1.30 P.M.: Temperature, 103.4° F.; 11 P.M.: Temperature, 101.4° F.

December 13th. 3 A.M.: Temperature, 102° F.; 9.30 A.M.: Temperature, 99.8° F.; 12 M.: Injection of 0.002 milligr.; 6 P.M.: Temperature, 103° F. Complains of constriction over diaphragmatic region.

December 14th. 9 A.M.: Temperature, 99.6° F.; 10.40 A.M.: Injection of 0.003 milligr.; 2 P.M.: Slight chill.

December 15th. 9.30 A.M.: Temperature, 100.8° F.; 4 P.M.: Injection of 0.002 milligr. Sensation of formication along back during night.

December 16th. 10 A.M.: Temperature, 101.6° F.; 5 P.M.: Injection of 0.002 milligr.

December 17th. 9 A.M.: Temperature, 100° F.; 5 P.M.: Injection of 0.002 milligr.

December 18th. 10.30 A.M.: Temperature, 100.6° F., expectoration more copious and easier; 5 P.M.: Temperature, 101.6° F.; injection of 0.002 milligr.

December 19th. 9 A.M.: Temperature, 99.2° F.; 5 P.M.: Temperature, 101° F.; injection of 0.002 milligr.

December 20th. 7 A.M.: Temperature, 99.8° F.; 12 M.: Temperature, 102.2 F.; 4.30 P.M.: Temperature, 101.2° F.; injection of 0.002 milligr.; 10 P.M.: Temperature, 101° F.

December 21st. 8 A.M.: Temperature, 99.4° F.; 9.30 to 10.10 A.M., had a slight chill of forty minutes' duration. 10.30 A.M.: Temperature, 102.8° F.; 12.30 A.M.: Temperature, 103.4° F.; 6 P.M.: Temperature, 101.8° F.

December 22d. 6 A.M.: Temperature, 99.2° F.; 4.15 P.M.: Temperature, 102.8° F.

CASE VI. *Tubercular Caries.*—Benjamin G——, aged twenty-two, admitted September 20, 1890. Present illness dates back four months, with symptoms of caries of left ankle-joint. Two months afterward suppurating sinuses. October 4, 1890, resection of ankle joint.

December 11th, he was subjected to treatment by lymph, as there was fear of tubercular disease, present in

joint. 12 M.: Temperature, 98.4° F.; injection of 0.001 milligr.; 8 P.M.: Temperature, 100° F.

December 12th. 11 A.M.: Temperature, 99.2° F.; injection of 0.002 milligr.; 8 P.M.: Temperature, 100° F.

December 13th. 11 A.M.: Temperature, 98.4° F.; 12 M.: Injection of 0.007 milligr.; 8 P.M.: Temperature, 100.4° F.

December 14th. 8 A.M.: Temperature, 100° F.; 10.40 A.M.: Injection of 0.006 milligr.; 7 P.M.: Temperature, 100° F.

December 15th. 11 A.M.: Temperature, 99° F.; 4.15 P.M.: Injection of 0.006 milligr.; 11 P.M.: Temperature, 98.2° F.

December 16th. 9 A.M.: Temperature, 98.2° F. Ceased to use the lymph after 4.15 P.M., December 15th, as there was no local change in the character of the suppurating operation wound, and it was, therefore, reasonable to suppose that all tubercular deposits had been removed by the surgical procedure.

CASE VII. *Lymphomata of Neck.*—Michael L——, aged twenty five. Came in with numerous lymphomata, involving both sides of neck. Dr. Beck removed all of them October 14, 1890, from the right side, and November 7, 1890, from left side of neck.

To remove doubts as to possible tuberculosis, December 11th, at 11.30 A.M., injection of 0.001 milligr.; 8 P.M.: Temperature, 104° F. Some expectoration.

December 12th. 11 A.M.: Temperature, 98.4° F.; injection of 0.002 milligr.; 8 P.M.: Temperature, 101° F. Some expectoration.

December 13th. 11 A.M.: Temperature, 99° F.; 12 M.: Injection of 0.003 milligr. Some expectoration.

December 14th. 2 A.M.: Temperature, 102 F.; 10.45 A.M.: Temperature, 99.4° F.; injection of 0.005 milligr.; 7 P.M.: Temperature, 102.2° F.

December 15th. 9 A.M.: Temperature, 99.4 F.; 4.15 P.M.: Injection of 0.006 milligr.

December 16th. 9 A.M.: Temperature, 100° F.

December 18th. Discharged from hospital.

CASE VIII. *Phthisis.*—John G——, aged fifty, had typhoid fever, 1860. Received wound in thigh in Civil War. Never had rheumatism. Present illness dates back three years; commenced with a cough and expectoration. Has lost considerable flesh the last eighteen months. Sleeps poorly. Percussion reveals, left side, posterior, flatness from apex to lower angle of scapula; right side, posteriorly, flatness down to middle of scapula; left side, anteriorly, supra-clavicular space, dulness almost to flatness; right side, anteriorly, dulness almost to flatness. Auscultation: Left posterior apex, harsh and prolonged expiratory murmur; right posterior apex, amphoric breathing.

In this case of old phthisis tuberculosa the injections with 0.001 milligr. were begun December 18th. The reaction thus far has been the usual one.

General Results.—Now as to the general results observed thus far. It is to be noted that we had to deal with severe symptoms of collapse in one case after the first injection; had a gradual fall instead of rise of temperature in the case of E. R—— after first injection. In all cases the patients' appetite and feeling of strength and comfort improved soon after the use of the injections; in the case of W. P—— there is no perceptible difference in the number of bacilli seen in the sputum now and before the injections were used. J. G——'s sputum shows now fewer and smaller tubercle bacilli than before the injections. Mrs. E. K—— has shown a smaller number of bacilli before and after injections. Miss E. R—— few bacilli but a large number of streptococci after first week of injections.

Her expectoration, which was scanty when she came on December 12th, is now quite considerable; râles moist, frequent; general condition improved very noticeably. Dulness of percussion pretty much the same as before. In only one of our cases has the percussion dulness anteriorly at the beginning of the second week of treatment.

The case of very slowly healing fistula in ano (operated upon) in a man of about forty-eight, who is not included in the above list, received three injections of 0.002 milligr. each in three succeeding days to determine the question: Tubercle or no? No reaction whatever taking place it is concluded that tuberculosis is not present.

Another healthy inmate of the hospital submitted to a few injections of 0.001 and 0.002 milligr. each, which were administered for comparative study. No reaction whatever could be noticed.

DR. L. WEBER, *Consulting Physician.*
S. G. KAHN, *Visiting Physician.*
GEO. W. RACHEL, *House Physician.*

DECEMBER 23, 1890.

CASES AT MONTEFIORE HOME FOR CHRONIC INVALIDS.

Service of DR. SIMON BARUCH.

(DR. MAX ROSENTHAL, House Physician.)

WE are not yet in a position to formulate definite conclusions regarding the promising discovery of Koch. The material now accumulated in our hospital is of great value and it behooves us to sift our results with great caution. My own data refer to 71 injections in 12 male and 9 female patients. The reaction was undoubted in every case, although not so pronounced as is reported in the cases from abroad. An element of fallacy must be excluded. Several of the cases, male and female, who had for a week previous to the injection presented a normal temperature, presented a rise of from one half to one and a half degree immediately preceding the injection. Every case of phthisis presented a rise of temperature within twenty-four hours; and one case of ulceration in the left cervical region, with fistulous canal, resisted a gradual advance until 5 milligr. were reached, when the temperature rose from 97.8° F. to 102.4° F. and has again fallen to 97.4° F. There is an increase in the discharge from the ulcerated surface; the patient's general condition is unchanged. One case presented a jaundiced discoloration of the skin, bleeding from the nose, with headache and nausea. His cough and expectoration decreased. In the majority of the cases cough and expectoration decreased, the latter becoming more mucoid, as Koch has demonstrated.

Nose-bleed occurred in two cases. Cough was diminished and expectoration increased in four cases. Decided nausea and headache occurred in eleven cases. Every case injected reached a normal temperature once or oftener.

The Course of the Treatment.—Pulse: The lowest pulse-rate recorded is 44; the highest 134. Respiration: The lowest respiration recorded is 17; the highest, 45. Temperature: The lowest temperature recorded 97.4° F.; the highest 103.2° F. Weight: Of eight male patients weighed, one lost one half pound, one lost one pound, one gained three-quarters pound, one gained one-half pound.

In face there is no difference. The most remarkable point in my experience is that in two cases, which were ready to be discharged on account of the abeyance of symptoms and physical signs and gain of weight (one gained twenty-one pounds and the other thirteen and one-half under hydrotherapy), there is loss of weight since the injection.

These cases would have been regarded as practically restored had not the Koch injection of one night produced a decided reaction. One of these cases is, perhaps, more completely affected by the lymph than any other. This, I regard, as a complete confirmation of Koch's claim of the diagnostic value of the injection in suspected tuberculosis.

47 EAST SIXTIETH STREET, December 23, 1890.

AT THE ST. FRANCIS HOSPITAL, NEW YORK.

Dr. George F. Shrady inoculated seven cases on Wednesday; two for tubercular disease of knee-joint; one for tubercular caries of wrist joint; one for carious sinus of thigh; one for scrofulous sinus of groin; one case of incipient phthisis, and one case of phthisis in second stage. The latter was a patient of Dr. John H. Ripley. The inoculations were prepared under the supervision of Drs. Max Einhorn and E. C. Wendt, and according to the strict Berlin method. Up to the time of going to press a sufficient period had not elapsed for reactions to occur.

The reports from the Mount Sinai and German hospitals were not received from Drs. Jacobi and Heineman in time to appear in this issue. Neither was that from Dr. Loomis giving the official account of cases treated in Bellevue Hospital We shall incorporate them with our account in our next issue.

In a general way it may be said that no new features have been developed. The reactions in the phthisis cases have been quite constant, as also in the cases of lupus, the latter having been reported as improving. The doses have generally been one milligramme, which has been cautiously increased in accordance with the amount of reaction produced. As yet no accidents nor serious complications have occurred in connection with the inoculations; neither has there been any death attributable to their use.

THE KOCH LYMPH BEFORE THE COUNTY MEDICAL SOCIETY.

DR. LINSLEY, at the meeting December 22d, gave an account of his recent trip to Berlin, where he had been sent by the Post-Graduate Medical School to study the action of the Koch lymph, and to secure some of the fluid for use in the hospital connected with that school. He witnessed the treatment at the Gehrhardt and Von Bergmann clinics. Both clinics were extremely crowded by students and doctors. At Gehrhardt's the patients were mostly those suffering from pulmonary tuberculosis, the disease usually being in the incipient stage, although he had seen the injections made in some advanced cases. His description of the reaction after the injections, and of the results obtained, corresponded with that already published in the medical journals. In the end the patients with pulmonary tuberculosis in the incipient stage were almost, without exception, apparently in better condition; the sputum became thinner, night-sweats disappeared. It was noted that the previous history, so far as he could learn, was not taken. The operator passed directly from one patient to the other, without each time again cleansing the needle. It would seem the inoculations would have to be continued for a period yet undetermined, but certainly until the patient ceased to show reaction after the injections. Professor Gehrhardt thought the outlook for the treatment was most encouraging, and that seemed to be the opinion of the profession throughout Berlin.

Von Bergmann presented patients whom he declared cured of lupus, from the milder to the more marked forms. The result was complete cicatrization of the ulcer in from two to six weeks. It could not be said that the ulcers would not break out again, but this would seem unlikely if fresh inoculations were made. As to the composition of the lymph, it was a matter solely of speculation. It was not likely to be made known soon. He thought one reason why it was held back was the fact that Koch himself was not yet fully satisfied, and was still experimenting. He could state on pretty good authority that the order in which it would be supplied to nations for use in hospitals and institutions was: Germany, Austria, Italy, America, then the other European countries. It was doubtful whether it would be supplied to individuals at all. As he had said, advanced cases of pulmonary tuberculosis were not regarded as suitable for this treatment, yet it had been practised in some cases, and he had attended some autopsies.

No Benefit in Phthisis.—Dr. Frederick Warner, who had spent two weeks in Berlin, leaving on the 13th inst., said that in the private course which he had been permitted to take, studying the effects of the inoculations on the tubercular cases in the hospital, he must admit to having seen no results worth mentioning. He added that, of course, most of the cases were of advanced phthisis. The only patient in whom he saw any good result was a man with tubercular laryngitis, who had, under the treatment, regained his voice. In enlargement of the glands of the neck, he had seen diminution in size by two-thirds. The most remarkable results, however, were noticed in cases of lupus. He mentioned one case in particular, that of a woman whose whole face, almost, was one ulcer; yet under the inoculations the healing process went on until an ulcer only the size of a pea was left. There remained no appearance of a scar, but good healthy tissue.

Dr. Simon Baruch gave some of the points in the treatment of twenty-one patients by the Koch lymph in the Montefiore Home. It seemed valuable in diagnosis. The curative results could not yet be determined.

Dr. Daniel Lewis showed a man with lupus about the eye whom he proposed to subject to the treatment and exhibit afterward.

Dr. A. H Smith thought it would be desirable to fix a standard for cases which were, and which were not, suitable for this treatment.

Dr. Linsley supposed that standard would be, for those suitable for the treatment, absence of pulmonary cavities; that is, incipient phthisis; yet he had seen, as previously stated, cases treated in every stage, and had witnessed one or two autopsies on patients who had had large cavities.

Got his Lymph Legitimately.—Dr. H. Holbrook Curtis said, with regard to the newspaper gossip as to how he had obtained his lymph, that he had come about it legitimately, and that it was the genuine lymph. It had come through a physician of undisputable integrity, who had obtained it in Berlin. He was not the only private person who had obtained the lymph, and he disclaimed being the first to use it in the country. What was of more importance was a knowledge of the action of the remedy, and he thought that our studies should begin with the blood. Koch had stated that the destruction of the leucocytes in the blood, in pernicious anæmia, was arrested by inoculation with this lymph. The subject, he thought, should be studied further from this point of view.

Sclerosis of the Lungs in Porcelain Workers.—Dr. Lemaistre has published a paper upon sclerosis of the lung as induced in the workers in porcelain. Sections of the lung are generally colored, according to the material that has been introduced; but here the lung is blackish, although the substance introduced may be white, owing to inflammatory conditions. The symptoms are analogous to tuberculosis, and the diagnosis is difficult. The posterior aspect of the lung is most frequently the seat of the sclerosis. Sometimes the sounds of pulmonary emphysema, or of pleurisy, may be heard. It is, however, differentiated from emphysema by the absence of tympanitic sounds. The sputa are characteristic. There is no hectic fever or nocturnal sweating. Men are more frequently attacked than women. He has found bacilli in the sputa, and regards the disease as a tubercular fibrosis. The silicious particles produce ulcerations in the bronchi, upon which the tubercular matter is grafted, and continues to exert an irritant action which induces hyperplasia of the connective tissue. This, to a certain extent, is salutary. Iodides constitute the best treatment in this form of sclerosis.—*Le Progrès Medical.*

Correspondence.

KOCH'S METHOD IN VIENNA.

(From our Vienna Correspondent.)

VIENNA, December 1, 1890.

It is now barely three weeks since Koch announced his discovery of a fluid possessing, when hypodermically injected, a specific power against tuberculous processes. But already, for ten days past—as soon as the mysterious compound could be brought here—experimentation has been going on daily in the clinics. The first cases injected were presented before the Vienna Medical Association. The interest was so great that the hall was packed, the aisles filled from door to platform, and many were unable to obtain even standing room. Dr. Hebra exhibited two cases of lupus, one of which showed the reaction typically. The whole skin was reddened by a scarlet erythema and the lupus patches on the hands were swelled and in spots necrotic looking. It was particularly interesting to observe that some old scars on the arms where the disease had seemed to be obsolete, had taken part in the reaction, and were red and swollen, indicating probably the persistence of tubercular material. Through the kindness of Professor Hebra, I have been able to follow this case from day to day. The second injection was given some four days after the first, and caused nearly as intense a reaction. The swollen, scabby lupus spots were then treated to a bath, and when softened sufficiently, were removed. The ulcers underneath looked healthy, red, and smooth, and began immediately to skin over. When they were nearly healed, a third injection was given. This caused a decided reaction, but not so profound as in the other instances. There is swelling and weeping of the lupus sites, but none of the angry, necrotic appearance previously noted.

Teachers in all departments are employing the new remedy. The extraordinary frequency of tubercular disease here is shown by the large number of cases of lupus and other tubercular skin lesions which crowd the clinics, and for which the hospital accommodations are too meagre, so that many must be bidden to wait. A number of cases of pulmonary tuberculosis have been inoculated, but the results are not yet determined. Professor Billroth has injected seven cases, including lupus, tubercular joint and bone disease, and tubercular abscess. On November 30th Professor Kaposi inoculated some thirteen cases of lupus, and, by way of control experiment, a number of cases of syphilis, one of sarcoma, and two of leprosy. The lupus cases all reacted severely, with chill, high temperature, delirium, and profound disturbances at the site of disease. None of the other cases reacted, except—which is very interesting—one of the lepra cases; the disturbances here were well marked, but not so profound as in the lupus cases.

No one that I have listened to here doubts that Koch's method produces astonishing results in lupus, but great caution is observed in regard to the acceptance of its effects as finally curative; and especially is much doubt expressed in reference to its action in pulmonary tuberculosis.

HOW THE INOCULATION IS MADE IN BERLIN.

(From our Special Correspondent.)

BERLIN, December 12, 1890.

From reports which have reached here from America it would appear that the methods used there are somewhat different from those employed here. At the risk, possibly, of repeating what may be a twice-told tale, it has occurred to me that a short description of the Berlin method might prove of passing interest. A description of the Koch syringe has already been given to you readers and need not be repeated. It will surprise some, perhaps, to learn that this instrument is not universally used even here, and that some prefer the ordinary hypodermic syringe which has, of course, been made aseptic. One reason for this is that the measuring of the quantities is easier of regulation and more accurate.

From the original Koch's lymph a small quantity (one cubic centimetre) is diluted ten times with a half per cent. solution of carbolic acid. This is marked accordingly as a ten per cent solution—is what may be called the "stock" solution from which the ultimate preparation for the injection is made. This is done by diluting the stock solution again ten times, *i.e.*, one cubic centimetre stock solution and nine cubic centimetres of solution of half per cent. of carbolic acid. This, then, is the one per cent. solution which is injected. Of this a decigramme of the Koch syringe will correspond with one milligramme of the original lymph, two decigrammes equalling two milligrammes, etc. This one per cent. solution will keep from eight to ten days, after which it loses its efficacy. This being the case it is always advisable that it should not be made in larger quantities than will be consumed in that period.

The rule here regarding the time and frequency of the inoculations is governed by the following circumstances: If after a small dose, which is considered to be a milligramme, neither the increased temperature nor any other reaction occurs within the first twenty-four hours, the inoculation can be repeated with twice the quantity. Some clinicians wait longer than that, sometimes for three days. If, however, the reaction is pronounced it is considered necessary to wait until the temperature and all other symptoms become normal, when the inoculation, in the same quantity, may be repeated. If after the second injection the temperature shows a tendency to fall from the first reaction, the third injection can be increased by one milligramme. I may say, in passing, that the usual rate of increase is one milligramme for each succeeding injection. When the reaction is very intense (106° F.) after the first inoculation the next injection must be reduced, and care must be taken that at the time of its administration all reactionary symptoms are absent. In general terms the size of the dose will depend upon the degree of reaction produced in different individuals. The usual quantity used in cases of phthisis is one milligramme, gradually increased to one centigramme. Occasionally it is even more than this. The rapidity of the increase depends upon the responding fall of the reaction, and, of course, varies in different individuals.

In surgical and lupus cases large doses have been given from the beginning, but at present there is a tendency, to be careful as to the amount even in these. The maximum dose for lupus, tubercular glands, and tubercular joints has been one centigramme, the minimum being one milligramme. Usually, however, a commencement is made with two milligrammes. It must be borne in mind that, even in what are supposed to be good cases for treatment, alarming symptoms may sometimes follow a first inoculation, such, for instance, as an unusually high temperature and threatened collapse. This circumstance has proved to be the strongest argument against the treatment of cases in private practice, which cannot be closely watched from hour to hour, as in the hospital ward. As far as I have learned, no case of death has occurred in this city as the direct result of the inoculation. This is explainable by the fact that prompt assistance has always been available when alarming symptoms showed themselves.

The duration of the inoculative treatment is generally from four to six weeks. By this must be meant that at the end of that period the reactions cease. It must be also understood that the case is not then considered cured, inasmuch, as a rule, the physical signs of phthisis still exist, and even the bacilli are found in the sputum. Therefore it is considered desirable to begin treatment in those incipient cases in which only small spots of the lung are affected, and in which the chances of repair are proportionately greater.

THE KOCH METHODS AT BERLIN.

To the Editor of the Medical Record.

[The following letter, just received from Dr. David Orr Edson, who is studying Professor Robert Koch's methods at Berlin, is of interest to the medical profession on this side of the water.]

Berlin, December 5, 1890.

. . . I am stopping at the Hotel Continental, and am sharing my rooms with Professor Samuel Dixon of the Bacteriological Department of the Jefferson Medical College of Philadelphia. I found it very difficult to obtain rooms, as the city is filled with physicians and tubercular patients. Dr. Dixon and I have been attending clinics and watching the effects of the "Koch substance," as it is called here. Yesterday we were invited by Dr. Golthdammer to visit his hospital (the Hospital Berthauer). This we did in the morning, and in the afternoon we made the rounds of the Charité Hospital, accompanied by Dr. Wilber a Wisconsin man, an assistant of Professor Koch, with whom he has been associated for the past four years. We saw many cases of pulmonary tuberculosis and lupus operated on by injection of the "substance," and also some very remarkable cures, or apparent cures, of tubercular disease of the knee- and hip-joint. It seems to me that these are the cases most favorably affected by the remedy.

The method of inoculation is as follows: One cubic centimetre of the original substance, which comes in vials holding 5 c.c. each, is diluted with 10 c.c. of boiled water (not distilled water), or with the same amount of solution of carbolized water. The first dose of this dilution should not be over two milligrammes in cases of pulmonary tuberculosis; but in cases of lupus 10 milligr. is the dose to commence with. Just before the inoculation this dilution is sterilized by heating over a spirit-lamp in a small test tube having a cotton plug inserted in its opening. The Koch hypodermic syringes are not being used in the hospitals I have visited, as they are considered unreliable and not capable of perfect sterilization. The ordinary hypodermic syringe is in vogue.

After the inoculation of a patient with pulmonary lesions, who was not much emaciated, but who gave physical signs of cavities in apex of right lung, and whose sputa were loaded with tubercle bacilli, the symptoms were increased temperature (103½° F.), increased expectoration, and an even greater number of baccilli in sputa, and pain over the areas of both lungs. This reaction occurred about four hours after inoculation. Subsequently these symptoms subsided, the temperature went to normal, and the amount of expectoration, cough, and the number of bacilli in the sputa diminished to below what was present before inoculation. The procedure is continued from day to day, the dose being increased until 100 milligr. of dilution are given. After this last dose no reaction is expected. The action on the system, is, I learn, one in which combustion plays a prominent rôle, nitrogenous substances being found very largely in all the excreta. A very great loss of strength and vital capacity follows after the reaction.

Low vitality is a contra-indication to the use of the Koch method in all cases.

Patients whose vital powers are good, however, soon rally from the depressant effects.

I saw in the Charité Hospital a case of "pernicious anæmia" treated with the "Koch substance." Koch, you perhaps know, advances the theory that pernicious anæmia is due to the action of the tubercle bacilli on the phagocytes, leucocytes, and red blood corpuscles. He got a marked reaction from the use of the substance in cases of this kind, and in this case the reaction was well marked. From this fact it is generally conceded here that the disease is of tubercular origin.

I have been watching the effect of the remedy on a typical case of lupus of the nose. The case was in the person of a young girl, aged eighteen, and the physical condition was excellent. The parts are much swollen, both nostrils being entirely closed and the tip of the nose destroyed by the disease. After the first injection of 10 c.c. she was put to bed, and two hours later her temperature had risen to 101° F., pulse 79, and a cough began. In the matter coughed up tubercular bacilli were found, which before inoculation were not present in the examined sputa. Her nose became horribly swollen and congested. This, however, soon subsided, and after three doses, given on successive days, the organ had decreased to its normal size and almost to its normal color; a bluish tint remained, which will probably be permanent.

A curious feature of this case, and one which I am told is a constant occurrence in all cases of lupus and of tubercular disease of knee, hip, or intestine or bladder, is that localized pulmonary pain and soreness invariably follows inoculation with the "substance," thus indicating latent pulmonary involvement.

The hospitals here are so overcrowded that the food and the attendance on patients is very bad, and the hygienic condition due to overcrowding worse. To go from the fresh air into a ward is enough to nauseat even me. In my opinion the outcome of this will be a terrible mortality.

Dr. Dixon was given an audience by Professor Koch day before yesterday. Dixon, as you know, published an article, over a year ago, which was copied extensively by American and English medical journals, in which he claimed to have cured surgical tuberculosis, *i.e.*, inoculated tuberculosis, in guinea-pigs by means of a product of the involution form of the tubercle bacillus. This article did not describe in detail Dixon's method of obtaining his substance. He has, however, described it to me in detail, giving me the test by which he determines its purity. I am greatly impressed with it, and believe it is practically identical with Koch's discovery. I am not at liberty to give it to you until I can obtain Dr. Dixon's consent. Koch questioned him very closely about it, and asked if he had inoculated into the human economy, to which Dixon replied, "No."

Koch told Dixon that cases of laryngeal tuberculosis gave the best results in treatment with his substance.

There has been considerable feeling engendered by the German press against Dixon, which was intensified by the English papers taking his part, and saying that if Koch's "substance" was a product of the tubercle germ, then to Dixon belonged the credit of priority of discovery.

Dixon published a card denying any intent on his part of robbing Koch of his glory, and after its publication he was sent for by the latter. Since his interview with Koch he has been the recipient of many calls and favors from eminent members of the profession here.

I would like to write much more, but time will not allow at present. You will, however, soon hear from me again. Yours, etc.,

David Orr Edson, M.D.

THE CO-EDUCATION OF THE SEXES.

To the Editor of the Medical Record.

Sir: The discussion of the question of the co-education of the sexes, by a symposium of medical gentlemen in a recent number of the *Medical News*, recalls my personal observations of the influence of a woman upon a medical class.

The first course of medical lectures which I attended was in a medical college in the interior of the State. The class, numbering about one hundred and fifty students, was composed largely of young men from the neighboring towns. They were rude, boisterous, and riotous beyond comparison. On several occasions the residents of the neighborhood sent written protests to the faculty, threatening to have the college indicted as a nuisance if the disturbances did not cease. During lectures it was often almost impossible to hear the professors, owing to the confusion.

Some weeks after the course began the Dean appeared before the class with a letter in his hand which he craved the indulgence of the students to be allowed to read. Anticipation was extreme when he announced that it contained the most extraordinary request which had ever been made to the faculty. The letter was written by a physician of Philadelphia, who requested the faculty to admit as a student a lady who was studying medicine in his office. He stated that she had been refused admission by several medical colleges, but as this institution was in the country, he thought it more likely to be free from prejudice against a woman medical student. The Dean stated that the faculty had taken action on the communication and directed him to report their conclusion to the class. The faculty decided to leave the matter in the hands of the class, with this understanding, that if any single student objected to her admission a negative reply would be returned. It subsequently appeared that the faculty did not intend to admit her, but wished to escape direct refusal by referring the question to the class, with a proviso which, it was believed, would necessarily exclude her.

But the whole affair assumed the most ludicrous aspect to the class, and the announcement was received with the most uproarious demonstrations of favor. A meeting was called for the evening, which was attended by every member. The resolution approving the admission of the lady was sustained by a number of most extravagant speeches, which were enthusiastically cheered. The vote was finally taken, with what seemed to be one unanimous yell "Yea!" When the negative vote was called a single voice was heard uttering a timid "No." The scene that followed passes description. A general rush was made for the corner of the room which emitted the voice, and the recalcitrant member was only too glad to acknowledge his error, and record his vote in the affirmative. The faculty received the decision of the class with evident disfavor, and returned an answer admitting the lady student. Two weeks or more elapsed, and as the lady student did not appear the incident of her application was quite forgotten, and the class continued in its riotous career. One morning, all unexpectedly, a lady entered the lecture-room with the professor, she was quite small of stature, plainly dressed, appeared diffident and retiring, but had a firm and determined expression of face. Her entrance into that Bedlam of confusion acted like magic upon every student. Each hurriedly sought his seat and the most absolute silence prevailed. For the first time a lecture was given without the slightest interruption, and every word could be heard as distinctly as it could if there had been but a single person in the room. The sudden transformation of this class from a band of lawless desperadoes to gentlemen, by the mere presence of a lady, proved to be permanent in its effects. A more orderly class of medical students was never seen than this, and it continued to be to the close of the term.

The real test of the influence of a woman upon the conduct and character of man in co-education was developed when the professor of anatomy came to that part of his course which required demonstrations that he believed should be witnessed only by men. The professor was a rollicking, jovial man, who constantly interspersed his lectures with witty remarks and funny anecdotes. Nor did he study to have his language chaste, or the moral of his stories pure and elevating. In fact, vulgarity and profanity formed a large part of his ordinary lectures, and especially was this true of the lectures on the branch of anatomy above mentioned. On this account, chiefly, he was exceedingly popular with the class, and during his lectures stamping, clapping, and cheering were the principal employments of the students.

One morning our lady student was missed at the lecture on anatomy, and the professor entered the room evidently laboring under great excitement. He stated that he had a communication to make to the class which demanded the most serious consideration. He then explained that he had thought it highly improper that the lady student should attend certain lectures specially adapted for men, and as he was approaching that subject he had frankly advised her to absent herself, in a letter which he read. He dwelt upon the indelicacy of the subject, the embarrassment under which he should labor if a lady were present, and the injustice which would be done to the class by the imperfect manner in which he should be obliged to demonstrate the subject. He closed by offering her abundant private opportunities for study and dissection. He then read her reply. It was gracefully written and showed a full appreciation of his embarrassing position, when viewed from the low stand point of impure and unchaste sentiments. But she could not conceive of a medical man whose mind was not so elevated and purified by the study of the science of anatomy that such sentiments would for a moment influence him. Coming to the practical question of her attendance upon these lectures, she declared that she paid for a full course, and that she was not to be thwarted by so trivial an objection as he had raised from receiving the full amount of instruction to which her tickets entitled her. If the professor would really be embarrassed by the presence of a lady's bonnet on the first tier of seats, she would take her seat on the upper tier, and remove her hat, and she trusted that his interest in his subject would lead him to entirely forget the presence of student No. 130—her registered number. At the close of the letter the professor acknowledged the justice of the rebuke which he had received, and declared that a lady who was animated by such elevated views of her profession was entitled to every possible encouragement which the class or faculty could give. He then opened the door, and she entered, only to receive an ovation of the most overwhelming character. The lectures on anatomy proceeded in regular order to their conclusion, and it was the universal testimony of the oldest students that they had never listened to such a complete and thorough course.

At the close of the term our lady student came up for examination for graduation, and took rank with the best students of the class. As this was the first instance of the granting of a medical diploma to a woman in this country, so far as the faculty had information, there was at first some hesitation about conferring the degree. But it was finally determined to take the novel step, and in the honor list of the roll of graduates for that year appears the name, Dr. Emily Blackwell.

Yours, etc.,

STEPHEN SMITH, M.D.

574 MADISON AVENUE.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 20, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	12	3
Scarlet fever	86	11
Cerebro-spinal meningitis	2	1
Measles	319	15
Diphtheria	114	37
Small-pox	0	0
Varicella	9	0
Pertussis	4	4

The Newspapers and Koch.—Far from being Kochsure on the consumption cure, the daily press is going off half-Koched, in its efforts to hit rumors on the wing.

Bequests to Pittsburg Medical Charities.—By the will of the late William Thaw there is given to the Allegheny Hospital, $20,000; Homœopathic Hospital, $25,000; Mercy Hospital, $20,000.
